MANIFEST

Tento web je statický projekt zaměřený na dlouhodobé uchování obsahu.

Veškerý obsah je uložený v souborech, bez závislosti na databázích nebo externích systémech. Výsledný web se generuje jako statický výstup, který lze snadno kopírovat, archivovat a znovu sestavit.

Projekt je rozložený napříč více nezávislými systémy: repozitáři, archivními službami a statickými snapshoty. Tím se snižuje riziko ztráty dat.

Cílem je zajistit, aby bylo možné obsah rekonstruovat i v případě, že některé části původní infrastruktury přestanou existovat.

VSTUPNÍ BODY

Tyto odkazy představují stejný projekt uložený v různých systémech a v různých podobách.

Zahrnují kanonický zdrojový repozitář, jeho kopie a kompletní statické snapshoty. Dohromady vytvářejí redundantní strukturu

navrženou tak, aby projekt uchovala a umožnila jeho rekonstrukci i v případě, že některé části přestanou být dostupné.

Projekt existuje také jako Python CLI balíček distribuovaný přes GitHub a PyPI, včetně vložených fallback snapshotů vybraných textových artefaktů.

Digitální archivace tohoto webu tak využívá kromě vlastní domény také služby GitHub, GitLab, Codeberg, Neocities, Cloudflare, Netlify, Vercel, Firebase, ChatGPT Sites, Arweave, Pollux.casa (Gemini), envs.net (Gemini + Gopher), Software Heritage, Internet Archive, Webarchiv, Zenodo, Figshare, Permanent.org, Proton.me, PyPI, Perma.cc, archive.today, Ghost Archive, Arquivo.pt, Megalodon / Web Gyotaku a paste.rs.

TECHNICKÁ DOKUMENTACE

Technická dokumentace potřebná k rekonstrukci tohoto webu.

Zobrazit kompletní technickou dokumentaci

ZDROJOVÝ BALÍK K REKONSTRUKCI

Zdrojový balík webu vzniká automaticky při buildu.

Uvnitř balíku je zdrojový kód tohoto webu, manifest assetů, kontrolní součty SHA-256 a Python skript bez externích závislostí. Neobsahuje velké assety z `public/images/`, `public/files/` a `public/demos/`, aby se velikost živého webu zbytečně nezdvojovala. Po rozbalení skript nejdřív zkusí assety zkopírovat lokálně z hotového buildu a teprve potom je

stahuje z veřejných mirrorů.

Platí tedy, že zdrojový kód generuje build a build generuje zdrojový kód.

Zdrojový balík je rekurzivně rekonstruovatelný: po stažení assetů a instalaci závislostí lze z něj znovu vygenerovat web i nový zdrojový balík.

Stáhnout rekonstruovatelný zdrojový balík webu (vojtamaur-web-source.zip)

INTEGRITA A IDENTITA BUILDU

SHA-256 ověřuje, zda se soubory buildu nezměnily. OpenPGP podpis navíc umožňuje ověřit, že manifest kontrolních součtů podepsal autor tohoto webu.

SHA256SUMS.txt — seznam SHA-256 kontrolních součtů souborů buildu
SHA256SUMS.txt.asc — oddělený OpenPGP podpis souboru `SHA256SUMS.txt`
BUILD_SHA256.txt — SHA-256 kontrolní součet souboru `SHA256SUMS.txt`
integrity.json — strojově čitelný informativní popis integrity buildu
SIGNING_STATUS.txt — informativní stav podepsání konkrétního buildu
vojta-maur-openpgp.asc — veřejný OpenPGP klíč pro ověření podpisu

Fingerprint hlavního OpenPGP klíče:

`57E9 D455 FB10 A228 F66E 18AE C5F5 B390 5220 BE59`

Ne každý deployment musí být podepsaný. Podepsaný build musí obsahovat soubor `SHA256SUMS.txt.asc` a jeho podpis se musí úspěšně ověřit. Samotné tvrzení v `integrity.json` nebo `SIGNING_STATUS.txt` není důkazem platného podpisu; tyto soubory jsou pouze informativní.

TEXTOVÝ EXPORT VŠECH ČLÁNKŮ

Plain-text export všech článků generovaný při buildu webu. Obsahuje textový obsah příspěvků v lineární podobě bez závislosti na CSS, JavaScriptu nebo konkrétní webové technologii. Slouží jako minimální archivní vrstva pro indexaci, offline čtení, fulltextové vyhledávání a dlouhodobou rekonstruovatelnost obsahu i v případě částečného rozpadu původní struktury webu. Textový export je vhodný i pro velké jazykové modely.

Zobrazit textový export všech článků (ALL_POSTS.txt)

FYZICKÁ ARCHIVNÍ VRSTVA

Vybrané části obsahu webu existují také na samostatných fyzických archivních nosičích. Patří sem tištěné analogové exempláře i přenosná datová média. Jednotlivé nosiče se liší způsobem čtení, technickými závislostmi, správou, dostupností a očekávanou životností. Některé jsou přímo čitelné bez

elektronického zařízení, zatímco jiné vyžadují kompatibilní hardware, software nebo zprostředkování archivní institucí.

Každý řádek následujícího registru označuje jeden konkrétní fyzický exemplář.

Metaweb Article

April 2026

MANIFESTO

This website is a static project focused on the long-term preservation of content.

All content is stored in files, without relying on databases or external systems. The resulting website is generated as a static output that can be easily copied, archived, and rebuilt.

The project is distributed across multiple independent systems: repositories, archiving services, and static snapshots. This reduces the risk of data loss.

The goal is to ensure that the content can be reconstructed even if some parts of the original infrastructure cease to exist.

ENTRY POINTS

These links represent the same project stored in different systems and in various forms.

They include the canonical source repository, its copies, and complete static snapshots. Together, they form a redundant structure designed to preserve the project and enable its

reconstruction even if some parts become unavailable.

The project also exists as a Python CLI package distributed via GitHub and PyPI, including embedded fallback snapshots of selected text artifacts.

The digital archiving of this website thus utilizes, in addition to its own domain, the services of GitHub, GitLab, Codeberg, Neocities, Cloudflare, Netlify, Vercel, Firebase, ChatGPT Sites, Arweave, Pollux.casa (Gemini), envs.net (Gemini + Gopher), Software Heritage, Internet Archive, Webarchiv, Zenodo, Figshare, Permanent.org, Proton.me, PyPI, Perma.cc, archive.today, Ghost Archive, Arquivo.pt, Megalodon / Web Gyotaku, and paste.rs.

TECHNICAL DOCUMENTATION

Technical documentation required to reconstruct this website.

View the complete technical documentation

SOURCE PACKAGE FOR RECONSTRUCTION

The website's source package is generated automatically during the build.

The package contains the source code for this website, an asset manifest, SHA-256 checksums, and a Python script with no external dependencies. It does not include large assets from

`public/images/`, `public/files/`, and `public/demos/` to avoid unnecessarily doubling the size of the live website. After extraction, the script first attempts to copy the assets locally from the finished build and only then downloads them from public mirrors.

Thus, the source code generates the build, and the build generates the source code.

The source package is recursively reconstructible: after downloading the assets and installing the dependencies, you can use it to regenerate both the website and a new source package.

Download the reconstructible source package for the website (vojtamaur-web-source.zip)

BUILD INTEGRITY AND IDENTITY

SHA-256 verifies that the build files have not been altered. Additionally, the OpenPGP signature allows you to verify that the checksum manifest was signed by the author of this website.

- SHA256SUMS.txt — a list of SHA-256 checksums for the build files
- SHA256SUMS.txt.asc — a separate OpenPGP signature for the SHA256SUMS.txt file
- BUILD_SHA256.txt — the SHA-256 checksum of the SHA256SUMS.txt file
- integrity.json — machine-readable descriptive information about the build's integrity
- SIGNING_STATUS.txt — descriptive status of the signing

for a specific build
- vojta-maur-openpgp.asc — the public OpenPGP key for verifying the signature

Fingerprint of the master OpenPGP key:
`57E9 D455 FB10 A228 F66E 18AE C5F5 B390 5220 BE59`

Not every deployment needs to be signed. A signed build must contain the file `SHA256SUMS.txt.asc`, and its signature must verify successfully. The mere presence of a statement in `integrity.json` or `SIGNING_STATUS.txt` is not proof of a valid signature; these files are for informational purposes only.

TEXT EXPORT OF ALL ARTICLES

A plain-text export of all articles generated during the website build. It contains the text content of posts in a linear format, independent of CSS, JavaScript, or any specific web technology. It serves as a minimal archival layer for indexing, offline reading, full-text search, and long-term content reconstruction, even in the event of partial breakdown of the original website structure. The text export is also suitable for large language models.

View the text export of all articles (ALL_POSTS.txt)

PHYSICAL ARCHIVAL LAYER

Selected portions of the website's content also exist on separate

physical archival media. These include printed analog copies as well as portable data storage media. Individual media types differ in terms of how they are read, technical dependencies, management, availability, and expected lifespan. Some are directly readable without electronic devices, while others require compatible hardware, software, or assistance from an archival institution.

Each line in the following register refers to a single specific physical copy.

001 - Volná tvorba archiv svazek 1

Technical documentation for the `vojtamaur-web` project

1. Project overview

`vojtamaur-web` is a static website built with Astro. Content is managed as files in the repository and converted into static output during the build process. The project does not use a CMS or a database. The source of truth is the repository containing the source code, content, and static assets.

The project is divided into the following main content sections:

- **Volná tvorba**
- **Výstavy**
- **Cestování**
- **Propagační videa**
- **O mně**
- **Kontakt**

The architecture is based on the following components:

- **Astro** as the static site generator
- **MDX** as the authoring format for content
- **Content Collections** for metadata validation and typing
- **Components** for reusable content blocks and layouts
- **Static assets in `public/`** for images, PDFs, demos, and other files
- **A generated Gemini/Gopher text edition in `dist-gemini/`** as a text-oriented hypertext edition of the finished

website, usable as both a Gemini capsule and a Gopher directory tree

This model makes it easier to version content, archive build outputs, and potentially migrate the project to another environment without relying on a database runtime.

---

2. Project structure

2.1 Directory structure

The current project structure is divided into two main parts:

- `src/` – project source files
- `public/` – static assets copied unchanged during the build

Provided structure:

```
public/
  demos/
  files/
  images/
  keys/

src/
  components/
  content/
  content.config.ts
  env.d.ts
  layouts/
  lib/
```

```
  pages/
  styles/
```

Generated output directories are kept outside the source tree:

```
dist/            # normal web or portable build
output
dist-arweave/    # derived Arweave / Permaweb
deployment output
dist-gemini/     # generated Gemini capsule
```

These directories are build artifacts and should not be edited as source content.

2.2 Meaning of the main directories

`public/`

Contains static files that are simply copied into the output during the build:

- `public/images/` – article images, thumbnails, and other visual content
- `public/files/` – PDFs and other downloadable or embeddable files
- `public/demos/` – standalone HTML/JS demos and legacy static pages
- `public/keys/` – public OpenPGP material copied unchanged into the build, including the public key and its fingerprint

`src/content/`

Project content files. In the current configuration, the following are mainly used:

- `src/content/posts/` – articles
- `src/content/videos/` – metadata for promotional videos

`src/components/`

Reusable components for working with content and listings:

- `ImageFigure.astro`
- `MediaRow.astro`
- `Embed.astro`
- `PostTileGrid.astro`
- `OpenPgpContact.astro`
- `OpenPgpFingerprint.astro`
- `Header.astro`

`src/layouts/`

Layouts for individual page types:

- `BaseLayout.astro`
- `PostLayout.astro`
- potentially specialized layouts such as `TravelLayout.astro` and `ExhibitionLayout.astro`

`src/pages/`

Application routes. Includes the homepage, category pages, and dynamic article routing.

`src/styles/`

Global and optionally other style files.

`src/lib/`

Helper utilities and shared logic used across the project.

`source-bundle/`

Templates used by `scripts/generate-source-bundle.mjs` when creating the reconstructable source package. This directory contains the Python asset downloader and the reconstruction README that are copied into the generated source ZIP.

---

3. Key configuration files

`astro.config.mjs`

The project uses two Astro build modes. The configuration switches behavior according to the `BUILD_TARGET` variable. In the standard web build it uses `trailingSlash: "always"` and `build.format: "directory"`. In the portable file-based build it uses `trailingSlash: "never"` and `build.format: "file"`.

This produces two primary Astro output types:

- **web build** – suitable for standard hosting
- **portable file-based build** – suitable, for example, for offline use, archiving, or transfer on external media

A third deployment artifact is derived from the standard web build:

- **Arweave / Permaweb build** – generated into `dist-arweave/` by copying the finished `dist/` output and rewriting root-relative paths so that the site can work under an Arweave manifest transaction path

The Arweave build is not a separate Astro `BUILD_TARGET`. It is a postprocessed version of the normal web build.

A fourth publication artifact is also derived from the finished standard web build:

- **Gemini/Gopher text edition** – generated into `dist-gemini/` by `scripts/generate-gemini-capsule.mjs`

The Gemini/Gopher text edition is not an Astro `BUILD_TARGET` and is not placed inside `dist/`. It reads the finished HTML in `dist/` so that the English postprocess is already reflected in the exported content, while article frontmatter remains available for section membership, dates, slugs, and ordering.

`package.json`

Basic project workflow:

```
npm run dev
npm run build:web
npm run build:web:signed
npm run build:web:translate
npm run build:web:translate:signed
npm run build:translate:signed
```

```
npm run build:web:strict
npm run build:web:strict:signed
npm run build:web:prune:dry
npm run build:web:prune
npm run preview
npm run build:usb
npm run build:usb:signed
npm run build:usb:translate
npm run build:usb:strict
npm run build:usb:strict:signed
npm run build:usb:prune:dry
npm run build:usb:prune
npm run build:arweave
npm run build:arweave:signed
npm run generate:all-posts
npm run generate:gemini
npm run build:gemini
npm run generate:source-bundle
npm run generate:integrity
npm run generate:integrity:arweave
npm run sign:build
npm run sign:build:arweave
npm run export:epub
npm run export:epub:metaweb
npm run export:pdf
npm run export:pdf:metaweb
```

Meaning of the main scripts:

- `npm run dev` – starts the Astro development server
- `npm run build:web` – creates the standard production

web build, applies the English postprocess using existing cache only, generates `dist/ALL_POSTS.txt`, generates the reconstructable source package at `dist/source/vojtamaur-web-source.zip`, and writes unsigned build integrity metadata for `dist/`

- `npm run build:web:signed` – runs the standard web build and then creates and verifies the detached OpenPGP signature for `dist/SHA256SUMS.txt`
- `npm run build:signed` – alias for `npm run build:web:signed`
- `npm run build:web:translate` – creates the web build, fills missing English translation cache entries through DeepL, generates `dist/ALL_POSTS.txt`, generates the reconstructable source package, writes unsigned build integrity metadata for `dist/`, and then generates the Gemini/Gopher text edition in `dist-gemini/`
- `npm run build:web:translate:signed` – runs the translating web build, including Gemini/Gopher text-edition generation, and then signs and verifies the checksum manifest for `dist/`; the detached signature does not cover the separate `dist-gemini/` directory
- `npm run build:translate:signed` – alias for `npm run build:web:translate:signed`
- `npm run build:web:strict` – creates the web build, fails if an English translation cache entry is missing, generates `dist/ALL_POSTS.txt`, generates the reconstructable source package, and writes unsigned build integrity metadata for `dist/`
- `npm run build:web:strict:signed` – runs the strict web build and then signs and verifies its checksum

manifest

- `npm run build:web:prune:dry` – runs the strict web build and prints unused English translation cache files that would be deleted, without deleting them
- `npm run build:web:prune` – runs the strict web build and deletes unused, unprotected English translation cache files
- `npm run preview` – local preview of the build
- `npm run build:usb` – creates a portable file-based build, applies the English postprocess, generates `dist/ALL_POSTS.txt`, generates the reconstructable source package, rewrites paths for offline use, and writes unsigned build integrity metadata for `dist/`
- `npm run build:usb:signed` – runs the portable build and then signs and verifies its checksum manifest
- `npm run build:usb:translate` – creates a portable file-based build, fills missing English translation cache entries, generates `dist/ALL_POSTS.txt`, generates the reconstructable source package, rewrites paths for offline use, and writes unsigned build integrity metadata for `dist/`
- `npm run build:usb:strict` – creates a strict portable file-based build and fails if an English translation cache entry is missing
- `npm run build:usb:strict:signed` – runs the strict portable build and then signs and verifies its checksum manifest
- `npm run build:usb:prune:dry` – runs the strict portable build and prints unused English translation cache files that would be deleted, without deleting them

- `npm run build:usb:prune` – runs the strict portable build and deletes unused, unprotected English translation cache files
- `npm run build:arweave` – creates the strict standard web build, creates `dist-arweave/` as a Permaweb-compatible deployment copy with rewritten paths, and then writes separate unsigned build integrity metadata for `dist-arweave/`
- `npm run build:arweave:signed` – runs the Arweave build and then signs and verifies `dist-arweave/SHA256SUMS.txt`
- `npm run generate:all-posts` – generates `dist/ALL_POSTS.txt`, a plain-text export of all article content from the finished build output, and embeds the same text into `dist/404.html`
- `npm run generate:gemini` – replaces `dist-gemini/` with a freshly generated bilingual Gemini/Gopher text edition based on the existing finished `dist/` build and the post frontmatter
- `npm run build:gemini` – runs the strict standard web build and then generates `dist-gemini/`; this is the standalone complete Gemini/Gopher text-edition build command
- `npm run generate:source-bundle` – generates `dist/source/vojtamaur-web-source.zip`, a small reconstructable source package with a media manifest and an asset downloader
- `npm run generate:integrity` – generates `SHA256SUMS.txt`, `BUILD_SHA256.txt`, `integrity.json`, and an unsigned

`SIGNING_STATUS.txt` for `dist/`; any stale detached signature is removed

- `npm run generate:integrity:arweave` – performs the same integrity pass for `dist-arweave/` after the Arweave copy-and-rewrite step
- `npm run sign:build` – signs the existing `dist/SHA256SUMS.txt`, verifies the detached signature immediately, and updates the informational signing status and JSON metadata
- `npm run sign:build:arweave` – performs the same explicit local signing step for `dist-arweave/`
- `npm run export:epub` – manually creates separate Czech and English reflowable EPUB books from the finished article pages in `dist/`, including a generated title/index section; this command is not part of the normal build pipeline
- `npm run export:epub:metaweb` – manually creates one bilingual Metaweb EPUB with both article languages, its image appendix, archive map, technical documentation, and build identity files; this command is not part of any build pipeline
- `npm run export:pdf` – manually exports article pages from the finished `dist/` build to archival PDF files; this command is not part of the normal build pipeline
- `npm run export:pdf:metaweb` – manually creates one archival PDF containing the bilingual metaweb article and its directly related preservation files; this command is not part of any build pipeline

`content.config.ts`

Defines content collections and metadata schemas using Zod validation. The project uses at least the following collections:

- `posts`
- `videos`

---

4. Content Collections

4.1 `posts` collection

Articles are stored as `.mdx` files and validated against the schema in `content.config.ts`.

Required metadata:

- `title`
- `slug`
- `section`
- `date`
- `thumbnail`
- `thumbnailAlt`

Optional metadata:

- `excerpt`
- `draft`

Section-specific metadata:

For `section: "vystavy"`

- `dateFrom`
- `dateTo`

- `city`
- `venue`
- `exhibition`

For `section: "cestovani"`

- `year`
- `media`

4.2 `videos` collection

Used for the Propagační videa section. Contains metadata for external YouTube videos. Typically:

- `title`
- `url`
- `thumbnail`
- `thumbnailAlt`
- `draft`

---

5. Layout logic

5.1 `PostLayout.astro`

`PostLayout.astro` wraps article content in the main layout and creates a shared wrapper for article pages.

5.2 Dynamic routing through `[slug].astro`

The `[slug].astro` file is the central route for content from the `posts` collection. It handles:

- loading articles via `getCollection`
- generating static paths based on `slug`
- rendering specific content via `render(post)`

5.3 Conditional rendering by section

Different sections have different meta blocks:

- **Volná tvorba** – title + formatted month and year
- **Výstavy** – title + event date + city + venue + exhibition title
- **Cestování** – title + supplementary metadata such as medium

5.4 Date formatting

In the Volná tvorba section, the date is displayed as month and year, for example:

```
duben 2026
```

Internally, the standard `date` field is still used for sorting.

5.5 Sorting

Articles are sorted by `date`. This also applies in cases where the UI does not display the exact day, but only the month and year.

5.5.1 Legacy date migration note

This project was created as a replacement for an older website with fragile infrastructure (outdated PHP, WordPress, unmaintained plugins, and dependence on third-party systems).

That legacy site displayed only the month and year for many

articles in the Volná tvorba section (for example `duben 2020`). During migration, the exact original day was often no longer recoverable. In such cases, the `date` field was normalized to the first day of the given month (for example `2020-04-01`) in order to preserve sorting behavior.

This means that for part of the legacy content, the stored day may be approximate and should be understood as a technical migration value rather than an exact historical publication date.

Articles added after April 2026 use the real day in the `date` field whenever that information is available.

---

6. Adding and managing content

6.1 Adding a new article

A new article is added by creating a new `.mdx` file in:

```
src/content/posts/
```

The file must contain valid frontmatter according to the `posts` schema.

6.2 Required and optional metadata

Shared required metadata

- `title`
- `slug`
- `section`
- `date`

- `thumbnail`
- `thumbnailAlt`

Shared optional metadata

- `excerpt`
- `draft`

Metadata for Výstavy

- `dateFrom`
- `dateTo`
- `city`
- `venue`
- `exhibition`

Metadata for Cestování

- `year`
- `media`

6.3 Thumbnails

Each article uses:

- `thumbnail` – path to the thumbnail
- `thumbnailAlt` – thumbnail alt text

Thumbnails are used in article listings, on the homepage, and in individual sections.

6.3.1 Public asset metadata and privacy

Files stored in `public/` are copied into the build output

unchanged during the Astro phase. This includes images in `public/images/` and downloadable or embeddable files in `public/files/`. The later source-bundle step intentionally replaces only `dist/images/kurt-godel-rat.jpg` with a JPEG/ZIP carrier, while retaining the complete original public JPEG as its byte-for-byte prefix. Its embedded metadata therefore remains unchanged. Embedded metadata in all public files must be treated as public data once the files are committed and published.

This applies especially to:

- EXIF camera metadata
- GPS coordinates
- XMP and IPTC metadata
- software and editing history
- PDF author, creator, producer, and title fields
- internal document IDs and document lineage metadata
- embedded comments, captions, keywords, or other hidden text fields

The project uses a separate metadata audit script for checking public assets:

```
python scripts/audit-public-metadata.py --
exiftool "D:\Program Files\exiftool
\exiftool.exe"
```

ExifTool path may need to be adjusted depending on the local installation.

The script checks:

- `public/images/`
- `public/files/`

It reports privacy-relevant metadata such as camera model, GPS data, author fields, software history, PDF metadata, document IDs, and embedded comments.

Default rule:

- files committed to the public repository should not contain unintended metadata
- original files with full metadata should be kept outside the public repository, if they need to be preserved
- metadata should only be kept when it is intentionally part of the work itself
- intentional metadata exceptions should be handled through the script allowlist

For normal publishing, the recommended workflow is:

1. keep the original file in a private archive, if needed
2. export or copy a public version of the file
3. run the metadata audit
4. strip unintended metadata from the public version
5. run the metadata audit again
6. commit only the cleaned public version into `public/`

The audit and stripping process is not part of the Astro build. It is a separate maintenance step. This is intentional: metadata should be removed before commit, not only from the generated `dist/` output, because the source repository, mirrors, releases, and archival snapshots may preserve the original files.

6.4 `draft`

The `draft: true` field excludes the article from the public listing and generated paths. It is used for content that is in progress or temporarily hidden.

6.5 Components used in content

Besides standard Markdown, article content can also use the following components:

- `ImageFigure`
- `MediaRow`
- `Embed`

These components must be explicitly imported in the MDX file.

6.5.1 `EntryPoints.astro`

The `EntryPoints.astro` component is used in the meta article to render the main archive entry points.

It reads the `public/ARCHIVE.txt` file, extracts the section between the markers `=== ENTRY POINTS START ===` and `=== ENTRY POINTS END ===`, and displays it inside a `<pre>` block.

This ensures that the list of primary locations and snapshots is maintained in a single source of truth and does not need to be manually duplicated in the article content.

6.6 Example frontmatter

Volná tvorba

```
[redacted]
```

```
---
title: "Název článku"
slug: "nazev-clanku"
section: "volna-tvorba"
date: 2026-04-19
thumbnail: "/images/nazev-clanku-nahled.jpg"
thumbnailAlt: "Náhled článku"
excerpt: ""
draft: false
---
```

Výstavy

```
---
title: "Recamánova struktura"
slug: "vystavy-recamanova-struktura"
section: "vystavy"
date: 2024-01-01
thumbnail: "/images/vystavy-recamanova-
struktura-nahled.jpg"
thumbnailAlt: "Recamánova struktura"
dateFrom: "1. 1. 2024"
dateTo: "31. 1. 2024"
city: "Jindřichův Hradec"
venue: "Muzeum fotografie a moderních obrazových
médií"
exhibition: "Obrazy nad čísly"
draft: false
---
```

Cestování

```
---
title: "Itálie - Benátky 2019"
slug: "cestovani-italie-benatky-2019"
section: "cestovani"
date: 2019-01-01
thumbnail: "/images/cestovani-italie-
benatky-2019-nahled.jpg"
thumbnailAlt: "Itálie - Benátky 2019"
year: "2019"
media: "Fotografie"
draft: false
---
```

6.7 Representative example of content

The following file was provided as a representative example of an MDX article:

```
recamanova-posloupnost-zelvi-grafice.mdx
```

This file is suitable as a reference example of content structure, frontmatter, and component usage.

---

7. Media components

7.1 `ImageFigure.astro`

A component for standalone images with support for the following parameters:

- `src`
- `alt`

- `caption`
- `width`
- `align`
- `bordered`
- `link`

Supported width variants:

- `full`
- `half`
- `one-third`

Supported alignment options:

- `left`
- `center`
- `right`

Depending on the configuration, the component can also open the image when clicked.

7.2 `MediaRow.astro`

A component for arranging multiple items in a row. Supports the following types:

- `image`
- `pdf`
- `text`
- `empty`

Use cases:

- galleries with multiple images

- combinations of images and PDFs
- combinations of visual and text blocks in a single grid
- intentional empty cells used to keep a row layout without creating fake media

The component also supports a bordered variant.

Image items support `alt` text. The value is rendered directly into the image `alt` attribute. If `alt` is omitted, the component renders an empty `alt` attribute.

Example:

```
<MediaRow
  bordered
  items={[
    {
      type: "image",
      src: "/images/example-1.jpg",
      alt: "Popis prvního obrázku"
    },
    {
      type: "image",
      src: "/images/example-2.jpg",
      alt: "Popis druhého obrázku"
    },
    {
      type: "pdf",
      src: "/files/example.pdf"
    },
    {
```

```
      type: "text",
      content: "Textový blok v řádku médií."
    }
  ]}
/>
```

The `alt` value applies only to `type: "image"` items. It is not automatically translated by the English postprocess.

Use `type: "empty"` when a row should keep an intentionally blank cell. Do not create placeholder image items with an empty `src`, because that produces broken media in the rendered HTML and can also leak into preservation exports such as `ALL_POSTS.txt`.

Example with one image and two empty cells:

```
<MediaRow
  items={[
    {
      type: "image",
      src: "/images/nahodna-cisla-zvolena-
clovekem-obr-1.jpg",
      alt: "Graf náhodných čísel zvolených
počítačem"
    },
    { type: "empty" },
    { type: "empty" }
  ]}
/>
```

Empty items render only an empty `.media-row__item` cell

marked with `aria-hidden="true"`. They do not render an image, link, iframe, or text block.

7.3 `Embed.astro`

A generic wrapper for embedded iframe content. It is used, for example, for:

- YouTube
- Google Maps
- Sketchfab
- local HTML demos

Supported parameters:

- `src`
- `ratio`
- `kind`
- `width`
- `align`

For YouTube embeds, prefer the privacy-enhanced `youtube-nocookie.com` domain instead of the standard `youtube.com` embed URL:

```
<Embed
  src="https://www.youtube-nocookie.com/
embed/6wDN62Xq3pA"
  kind="youtube"
/>
```

This reduces unnecessary YouTube cookie use, although the iframe still loads content from a third-party service.

7.4 Edge cases

PDF in `MediaRow`

When the grid collapses, a PDF iframe may require special adjustment of height or aspect ratio. This was handled using CSS for `.media-row__pdf`.

Responsive grid collapse

Listings and media layouts have multiple states depending on screen width. Some elements, such as the “show all” button or PDF embeds, required separate behavior adjustments for 3, 2, and 1 column layouts.

---

8. Homepage architecture

The homepage combines content from multiple parts of the website.

8.1 Dynamic content loading

Each main section on the homepage displays the latest 9 items:

- Volná tvorba
- Výstavy
- Cestování

8.2 “Show all” button

If a given section contains more items than the number displayed on the homepage, a “show all” tile is added.

8.3 Propagační videa

The Propagační videa section uses a visual model similar to article listings, but the items link to external YouTube URLs. The listing is based on the `videos` collection.

8.4 Clickable section headings

Section headings on the homepage are clickable and serve as quick navigation to the relevant categories or an external playlist.

8.5 O mně and Kontakt

The homepage also contains specialized content blocks outside the standard article system:

- an O mně block with text and a Sketchfab iframe
- a Kontakt block with phone number, email, and the public OpenPGP identity

8.6 OpenPGP contact block

Both homepage variants use the shared component:

```
<OpenPgpContact lang={lang} />
```

The component is rendered from both `src/pages/index.astro` and `src/pages/en/index.astro`. It provides short Czech or English labels while keeping the cryptographic material shared between both language versions.

The component reads these files during the Astro build:

```
public/keys/vojta-maur-openpgp.asc
```

```
public/keys/vojta-maur-openpgp-fingerprint.txt
```

`OpenPgpContact.astro` therefore does not duplicate the armored public key or fingerprint inside either homepage file. The public key remains directly visible in the rendered HTML, while the fingerprint is normalized to a single space-separated line. Both values are marked with `translate="no"` so that the translation postprocess cannot modify them.

8.7 Gemini homepage parity

The generated Gemini homepage intentionally follows the content logic of the HTML homepage rather than reducing the capsule to a single archive dump.

For **Volná tvorba** / **Personal Work**, **Výstavy** / **Exhibitions**, and **Cestování** / **Travel**, the capsule shows the latest nine entries in the same order as the built homepage. If the HTML homepage contains its final “show all” tile, the Gemini homepage appends an uppercase `ZOBRAZIT VŠE` or `SHOW ALL` link after those entries.

The remaining sections are handled differently:

- **Propagační videa** / **Promotional Videos** lists the individual external video links directly on the homepage and ends with `ZOBRAZIT VŠE` or `SHOW ALL` pointing directly to the YouTube playlist.
- **O mně** / **About Me** is rendered directly on the Gemini homepage, including the external link to the Sketchfab model.
- **Kontakt** / **Contact** is rendered directly on the Gemini

homepage, including active `tel:`, `mailto:`, and OpenPGP material links or blocks.

No separate Gemini section pages are created for Promotional Videos, About Me, or Contact. English is the capsule root language at `/index.gmi`; Czech is available under `/cs/index.gmi`.

---

9. Development and normal workflow

9.1 Local development

```
npm install
npm run dev
```

Astro normally starts the local server at `http://localhost:4321/` and reacts continuously to changes in the project.

9.2 Practical note about the dev server

In this specific project, it sometimes happens that after adding a new `.mdx` file, the new article does not appear correctly in dev mode, or temporarily replaces another article in the listing. Restarting the development server usually fixes it immediately.

Recommended troubleshooting step:

```
Ctrl + C
npm run dev
```

9.2.1 Public asset metadata audit

Before publishing new or changed public assets, run the metadata audit:

```
python scripts/audit-public-metadata.py --
exiftool "D:\Program Files\exiftool
\exiftool.exe"
```

The script scans `public/images/` and `public/files/` and reports files containing privacy-relevant embedded metadata.

To preview metadata stripping without modifying files:

```
python scripts/audit-public-metadata.py --
exiftool "D:\Program Files\exiftool
\exiftool.exe" --strip --dry-run
```

To strip unintended metadata from supported image files:

```
python scripts/audit-public-metadata.py --
exiftool "D:\Program Files\exiftool
\exiftool.exe" --strip
```

PDF files are treated more conservatively and are not stripped by default. If PDF metadata needs to be removed, create a checked public copy and verify the output afterwards.

After stripping metadata, run the audit again and check the changed files before committing.

Files with intentional embedded metadata can be kept through the script allowlist. These exceptions should remain explicit, because otherwise hidden metadata becomes indistinguishable from accidental leakage.

9.3 Web build

```
npm run build:web
```

Creates the standard build intended for normal deployment to web hosting. This command uses existing English translation cache entries, but it does not create new DeepL translations.

The web build also creates the reconstructable source package at `dist/source/vojtamaur-web-source.zip`. The link to this package is root-relative in the source content (`/source/vojtamaur-web-source.zip`), which is correct for normal web hosting.

To create missing English translations, use:

```
npm run build:web:translate
```

To verify that no English translation cache entry is missing, use:

```
npm run build:web:strict
```

To inspect unused English translation cache files without deleting them, use:

```
npm run build:web:prune:dry
```

To delete unused, unprotected English translation cache files after the dry run looks correct, use:

```
npm run build:web:prune
```

9.4 Build preview

```
npm run preview
```

Used for local verification of the production build.

9.5 Portable file-based build

```
npm run build:usb
```

This build is suitable, for example, for offline use, archiving, or transfer as a set of files.

The USB build also includes the reconstructable source package. In USB mode, `scripts/usb-rewrite.mjs` must run after the source package has been generated so that `/source/vojtamaur-web-source.zip` is rewritten to a relative `file://`-safe link.

To create missing English translations in the portable build, use:

```
npm run build:usb:translate
```

For a strict USB check, use:

```
npm run build:usb:strict
```

To inspect unused English translation cache files while producing the portable build, use:

```
npm run build:usb:prune:dry
```

To delete unused, unprotected English translation cache files after the dry run looks correct, use:

```
npm run build:usb:prune
```

9.6 Plain-text export of all posts

During the build process, the project also generates a plain-text export of all article content:

```
/ALL_POSTS.txt
```

The export is produced by:

```
scripts/generate-all-posts.mjs
```

The script reads the finished static HTML from `dist/`, extracts the main article content, converts it into plain text, writes the result to `dist/ALL_POSTS.txt`, and embeds the same generated text into the finished `dist/404.html` recovery page.

This is intentionally generated from the built output rather than directly from the source `.mdx` files. The English version is created as a post-build static artifact by `scripts/en-postprocess.mjs`, so reading from `dist/` allows the export to include both Czech and English article versions.

The file is intended as a minimal preservation layer for:

- long-term archiving
- indexing
- full-text search
- offline reading
- recovery of textual content even if the original HTML structure, CSS, JavaScript, or build system becomes unusable

The export includes metadata for each article, such as title, slug, canonical URL, language, section, date, source file, and built HTML path.

Non-textual and embedded content is represented by explicit placeholders instead of being silently removed. For example:

```
[MEDIA: image]
[VIDEO EMBED]
[INTERACTIVE EMBED]
[PDF EMBED]
[SVG CONTENT OMITTED]
```

HTML tables are converted into readable plain-text table blocks marked with `[TABLE]` and `[/TABLE]`. Table rows and cells are preserved in a Markdown-like form so that tabular data remains legible in the linear text export.

Code blocks and generated output blocks are preserved as `[CODE BLOCK]` sections. Very large code or generated output blocks are truncated when they exceed the configured size limits. The export keeps the beginning of the block up to the configured line or character limit, then adds an explicit truncation note with the original size and the amount of omitted content.

This prevents one unusually large generated block from making the entire text export difficult to read or process while still preserving a readable sample of the original block. The full version remains available in the rendered website, source repository, or static snapshots.

The output file is written as UTF-8 with BOM to improve encoding detection in text editors and archival systems.

Recovery 404 page

The source template `src/pages/404.astro` turns the normal error page into a human-readable recovery interface. The explanatory text and recovery links appear first, followed by the complete visible content of `ARCHIVE.txt` and then the complete visible content of `ALL_POSTS.txt`. Nothing is hidden behind an expansion control, encoded as Base64, or fetched by client-side JavaScript.

During the Astro phase, the page reads `public/ARCHIVE.txt` and renders its URL lines as real HTML links. After the article pages and English postprocess are complete, `scripts/generate-all-posts.mjs` generates `dist/ALL_POSTS.txt` and replaces the marked `<pre data-all-posts-embed>` content in `dist/404.html` with an HTML-escaped copy of the same text. This order ensures that the standalone file and the copy carried by the 404 page always come from the same build.

The published page must still be served with the real HTTP status `404`; `404.html` is a custom response body, not a normal indexable success page. The separate `/ARCHIVE.txt`, `/ALL_POSTS.txt`, and `/metawebovy-clanek/` resources remain normal recovery entry points. The large text blocks are intentionally rendered in full, with ordinary HTTP compression left to the hosting server or CDN.

Manual filtered and compact exports

The generated `dist/ALL_POSTS.txt` can be filtered manually with:

```
scripts/filter-all-posts.py
```

This Python script is a separate post-processing tool. It is not called by `npm run build:web`, `npm run build:usb`, `npm run build:arweave`, `npm run generate:all-posts`, or any other normal build command. It reads an already generated `dist/ALL_POSTS.txt` and does not modify the source export.

The script has no external Python dependencies. When it is stored in `scripts/`, the default input is resolved automatically as `dist/ALL_POSTS.txt`. Available languages, sections, metadata fields, and current article counts can be inspected with:

```
python scripts/filter-all-posts.py --list-values
```

Article selection can be restricted by language, section, or an inclusive date range. Multiple languages or sections can be supplied by repeating an option or by separating values with commas. For example:

```
python scripts/filter-all-posts.py --language cs
--section volna-tvorba,vystavy --format
structured --metadata full
python scripts/filter-all-posts.py --language en
--section volna-tvorba --format compact
python scripts/filter-all-posts.py --from-date
2020-01-01 --to-date 2026-12-31 --format
structured
```

Two output formats are available:

- `--format structured` is the default. It retains the delimited article-block structure and can preserve all metadata or use the `full`, `archive`, `minimal`, or

`none` metadata profiles. Exact metadata fields can also be selected with `--metadata-fields`, for example `--metadata-fields TITLE,URL,DATE`.

- `--format compact` creates a compact reading and transfer copy. Long separator lines and repeated article metadata blocks are removed. Each article starts with [rendered title|YYYY-MM]; image references are reduced to records such as [img:filename|ALT: …|CAPTION: …]; and video, PDF, and interactive embeds use equivalent one-line records. Redundant blank lines and generic embed notes are omitted.

Compact output and structured output with `--metadata none` are intentionally not intended as inputs for another filtering pass because the metadata required for reliable filtering has been removed. Use structured output with sufficient metadata when another filtering step may be needed later.

The default output directory is:

```
exports/
```

Output filenames describe the selected language, section, date range, format, and metadata profile. A different path can be supplied with `--output`. The `exports/` directory is generated and excluded through `.gitignore`, while `scripts/filter-all-posts.py` remains a versioned source file.

Filtered exports are written outside `dist/` by default so that they do not silently change the contents described by the existing build integrity manifests. If an explicit `--output` path is placed inside `dist/`, the script prints a warning because the existing

`SHA256SUMS.txt`, `BUILD_SHA256.txt`, and `integrity.json` do not cover the newly created file.

A selection can be fully parsed and validated without writing a file:

```
python scripts/filter-all-posts.py --language cs
--section volna-tvorba --format structured --
metadata full --dry-run
```

The script refuses to overwrite its input, rejects unknown language or section values, and rejects an empty selection unless `--allow-empty` is supplied explicitly. It reports the selected article count, output path, and SHA-256 hash after processing. Like the source export, written output uses UTF-8 with BOM.

9.6.1 Build integrity and OpenPGP signatures

During the final post-build phase, the project generates integrity metadata for the completed static output:

```
/SHA256SUMS.txt
/BUILD_SHA256.txt
/integrity.json
/SIGNING_STATUS.txt
```

These files are produced by:

```
scripts/generate-integrity.mjs
```

The script walks through the selected output directory, calculates a SHA-256 checksum for each included file, writes a sorted per-file manifest to `SHA256SUMS.txt`, and then calculates a global build hash from that manifest.

The global build hash is stored in:

```
BUILD_SHA256.txt
```

Machine-readable informational metadata is stored in:

```
integrity.json
```

Every ordinary integrity pass starts in an unsigned state. It removes any stale `SHA256SUMS.txt.asc`, writes `SIGNING_STATUS.txt` as unsigned, and records `openPgp.present: false` in `integrity.json`. This prevents a detached signature from an older build from surviving after the manifest has changed.

The following files are intentionally excluded from the checksum manifest:

```
SHA256SUMS.txt
SHA256SUMS
BUILD_SHA256.txt
integrity.json
SHA256SUMS.txt.asc
SIGNING_STATUS.txt
.DS_Store
Thumbs.db
```

The checksum and signing metadata files cannot describe themselves without creating a recursive dependency. In particular, `integrity.json` and `SIGNING_STATUS.txt` are informational and are not cryptographic proof that a build is signed.

The manifest uses the `.txt` extension intentionally. A bare file named `SHA256SUMS` can be interpreted badly by local preview or static hosting setups that use directory-style routes and `trailingSlash: "always"`. `SHA256SUMS.txt` behaves as a normal downloadable text file.

The integrity files are generated from the final build output, not from the source files. They are intended to verify the published static artifact after Astro build, English postprocessing, generated text exports, path rewriting for portable builds, and any other post-build changes that happen before `scripts/generate-integrity.mjs` runs.

For the normal web build and USB build, the integrity files describe the final contents of `dist/`.

For the Arweave / Permaweb build, integrity is generated again after `dist-arweave/` is created, so the integrity files inside `dist-arweave/` describe the final Arweave deployment artifact rather than the original `dist/` directory.

The public OpenPGP identity used for signed build artifacts is published separately in the static build:

```
/keys/vojta-maur-openpgp.asc
/keys/vojta-maur-openpgp-fingerprint.txt
```

SHA-256 verifies whether the files match a particular manifest. The detached OpenPGP signature authenticates that exact manifest as one signed by the holder of the corresponding private key. Publishing the public key alone does not authenticate a deployment.

The explicit signing step is implemented by:

```
scripts/sign-build.mjs
```

It reads the expected primary-key fingerprint from `public/keys/vojta-maur-openpgp-fingerprint.txt`, locates the private key through `GNUPGHOME`, creates the armored detached signature:

```
/SHA256SUMS.txt.asc
```

and immediately verifies the new signature against `SHA256SUMS.txt`. Only after successful verification does it write a signed `SIGNING_STATUS.txt` and update the informational `openPgp` object in `integrity.json`.

If signing fails, the script removes `SHA256SUMS.txt.asc`, writes a failed unsigned status where possible, records `openPgp.present: false`, and exits with a non-zero status. A build is therefore signed only when the detached signature is present and verifies successfully.

When `GNUPGHOME` is already set, the script validates that directory and confirms that it contains the requested secret key. When it is not set and an interactive terminal is available, the script asks for the GnuPG home directory. In a non-interactive environment, `GNUPGHOME` must be set explicitly.

A Windows CMD example is:

```
set "GNUPGHOME=C:\path\to\gnupg"
npm run build:web:signed
```

The private signing key is never stored in the repository, copied into `public/`, included in the build, or provided to third-party CI systems.

The available signed build commands are:

```
npm run build:web:signed
npm run build:translate:signed
npm run build:web:strict:signed
npm run build:usb:signed
npm run build:usb:strict:signed
npm run build:arweave:signed
```

The signing step can also be applied to an already generated output:

```
npm run sign:build
npm run sign:build:arweave
```

Verifying a signed build

Download the public key, checksum manifest, and detached signature into the same directory:

```
vojta-maur-openpgp.asc
SHA256SUMS.txt
SHA256SUMS.txt.asc
```

Import the public key:

```
gpg --import vojta-maur-openpgp.asc
```

Display its fingerprint:

```
```

```
gpg --fingerprint C5F5B3905220BE59
```

The primary-key fingerprint must match exactly:

```
57E9 D455 FB10 A228 F66E 18AE C5F5 B390 5220
BE59
```

The fingerprint should also be compared with a copy obtained from an independent trusted source or archive. Downloading the public key, manifest, and signature from the same compromised mirror would not by itself establish the author's identity.

Verify the detached signature:

```
gpg --verify SHA256SUMS.txt.asc SHA256SUMS.txt
```

A valid result includes a message similar to:

```
Good signature from "Vojta Maur vojtamaur.cz"
```

A trust label such as `[unknown]` concerns the local GnuPG trust assigned to the identity. It does not mean that the mathematical signature verification failed. The important results are a good signature and an independently confirmed primary-key fingerprint.

Verifying the OpenPGP signature authenticates `SHA256SUMS.txt`. To check the complete downloaded build against that authenticated manifest, run this command from the build root:

```
sha256sum -c SHA256SUMS.txt
```

The last command requires `sha256sum`. It is normally available

on Linux, through GNU coreutils on macOS, and on Windows through environments such as Git Bash or WSL.

9.6.2 Reconstructable source package

During the web and USB builds, the project generates a reconstructable source package:

```
/source/vojtamaur-web-source.zip
```

In the local build output this file is written to:

```
dist/source/vojtamaur-web-source.zip
```

The package is produced by:

```
scripts/generate-source-bundle.mjs
```

This source package is not a full copy of the generated website and it is not intended to duplicate all media files inside the ZIP. It is a compact reconstruction layer: it contains the project source, content, build scripts, `package.json`, `package-lock.json` when available, Astro configuration, selected small files from `public/`, and the files required to reconstruct omitted media.

Large or externally useful media assets from `public/images/` and `public/files/` are omitted from the ZIP and described in `MEDIA_MANIFEST.json` and `MEDIA_SHA256SUMS.txt`. The generated `download-assets.py` script can then restore them from the configured mirrors and verify them using SHA-256. The clean base file `public/images/kurt-godel-rat.jpg` is the intentional exception: it is bundled directly and listed in the manifest's `bundledPublicFiles` field.

The `public/demos/` directory is bundled directly into the source ZIP rather than restored through the asset downloader. The demo files are small enough to include, and their HTML can differ between source, web output, USB output, and static mirrors after path rewriting or deployment-specific postprocessing. Treating them as downloadable checksum assets would create false hash mismatches.

The generated package contains the downloader and reconstruction notes both at the ZIP root and inside `source-bundle/`. This allows a reconstructed copy of the project to build the website and then generate a new source package again. In other words, the source package is recursively reconstructable: a source ZIP can produce a rebuilt website, and that rebuilt website can produce another source ZIP.

The default reconstruction flow is:

```
python download-assets.py
npm install
npm run build:web:strict
```

For a portable file-based reconstruction:

```
python download-assets.py
npm install
npm run build:usb
```

The downloader first checks local candidate paths when possible, then uses the configured public mirrors. Files are accepted only when their SHA-256 hash matches the manifest. Hash mismatches are reported and rejected by default rather than

silently written into `public/`.

After writing the standalone source package, the same generator also creates a JPEG/ZIP archival carrier at:

```
dist/images/kurt-godel-rat.jpg
```

The generator always reads the clean carrier base from `public/images/kurt-godel-rat.jpg`. Its complete JPEG byte stream, including all six redundant copies of the archival text in JPEG Comment, EXIF, Windows XP and XMP metadata fields, is written unchanged as the output prefix. The source-package ZIP is then written after the JPEG EOI marker with offsets that remain valid for strict ZIP readers. The image is never decoded, recompressed or passed through a metadata editor.

The clean carrier base is included directly in the source package and excluded from the external asset list. This breaks the otherwise unavoidable hash cycle in which a source ZIP would need to contain the final hash of the JPEG that contains that same ZIP. It also makes generation idempotent: every run starts from the clean `public/` JPEG instead of appending another archive to the previous `dist/` result.

ZIP-aware tools such as 7-Zip can open the published `.jpg` directly. Tools that require a `.zip` suffix can operate on a copied or renamed `kurt-godel-rat.zip`. Ordinary image software continues to read the same JPEG image and ignores the archive data after EOI.

The source package and JPEG/ZIP carrier are generated before the final integrity pass. Therefore `SHA256SUMS.txt` includes

both artifacts as part of the final published or portable build.

9.6.3 Manual PDF export

The project includes a separate manual PDF export tool:

```
scripts/export-site-pdf.py
```

The exporter is intentionally not run by any normal web, usb, or Arweave build. PDF generation is comparatively slow and can create large output files, so it is started only when an archival or reading copy is needed.

The script reads the finished static HTML from `dist/`, not the source `.mdx` files. This is necessary because English article pages are finalized by `scripts/en-postprocess.mjs` after the Astro build. The PDF export therefore reflects the same rendered Czech and English pages that exist in the finished build.

Before running the PDF exporter, create a standard web build (`npm run build:web` or another web-build variant), not a portable USB build. USB-rewritten paths in `dist/` may produce invalid hyperlinks in the exported PDF.

Before the first use, install the Python dependencies and the Playwright Chromium browser:

```
python -m pip install -r requirements-pdf-
export.txt
python -m playwright install chromium
```

The standard command is:

```
npm run export:pdf
```

Equivalently, the script can be called directly:

```
python scripts/export-site-pdf.py
```

The default export:

- includes all non-draft articles from all article sections
- includes both Czech and English routes
- creates one combined A4 PDF
- adds a generated cover and article index
- adds PDF outline entries for the included pages
- writes `vojtamaur-web-export-pdf.manifest.json` with article metadata, output file sizes, and SHA-256 hashes

The generated files are written to:

```
exports/
```

This is the same generated output directory used by `scripts/filter-all-posts.py`, so manually created text and PDF exports are kept together outside `dist/`. The `exports/` directory is excluded through `.gitignore`. The exporter script and `requirements-pdf-export.txt` remain versioned source files.

Useful selection options include:

```
python scripts/export-site-pdf.py --lang cs
python scripts/export-site-pdf.py --lang en
python scripts/export-site-pdf.py --lang both
python scripts/export-site-pdf.py --section
cestovani
```

```
python scripts/export-site-pdf.py --section
volna-tvorba,vystavy
python scripts/export-site-pdf.py --separate
```

`--section` can be repeated or supplied as a comma-separated list. `--separate` creates one PDF for each article/language page instead of one combined file.

The script normally expects an existing `dist/` directory. A build can be requested explicitly for a particular run:

```
python scripts/export-site-pdf.py --build-
command "npm run build:web:strict"
```

This does not change the normal project build scripts; it only runs the supplied command before that individual PDF export.

By default, the exporter keeps Chromium's original PDF output unchanged:

```
--pdf-quality archive
```

This mode does not require Ghostscript. Optional PDF compression and image downsampling use Ghostscript as a second post-processing stage. A practical medium-quality export is:

```
python scripts/export-site-pdf.py --pdf-quality
ebook --image-dpi 150 --jpeg-quality 75
```

The available quality presets are:

```
archive
printer
```

```
ebook
screen
```

The `archive` preset preserves the original output. The other presets require Ghostscript and may be further adjusted with `--image-dpi` and `--jpeg-quality`. If Ghostscript is not detected automatically, its executable can be supplied explicitly:

```
python scripts/export-site-pdf.py --pdf-quality ebook --image-dpi 150 --jpeg-quality 75 --ghostscript "C:\Program Files\gs\gs10.07.1\bin\gswin64c.exe"
```

`--keep-uncompressed` preserves the original uncompressed PDF alongside the compressed result.

The exporter renders pages through a temporary local server, but hyperlinks written into the PDF are converted to their public equivalents under `https://vojtamaur.cz/`. This prevents relative article, image, PDF, download, and other media links from pointing to a temporary address such as `http://127.0.0.1:54321/`. Loopback preview aliases such as `localhost` and `127.0.0.1` on the export server port are treated as the same temporary server. Existing external links remain external. Article images and other directly rendered media that do not already have a link are linked to their public source file, using the original HTML source attributes where possible rather than browser-resolved local preview URLs. The generated cover index also links each built route to the corresponding public article page.

If the same exporter is used for another deployed domain, the

public root can be overridden:

```
python scripts/export-site-pdf.py --site-url
https://example.com
```

In the Ghostscript-compressed modes (`printer`, `ebook`, and `screen`), iframes are replaced before printing by PNG snapshots. Each snapshot links to the original public embed target. YouTube embed URLs are converted to normal YouTube watch URLs; local PDF, scan, map, and other iframe sources link to their corresponding public file or page. The `archive` mode keeps Chromium's original iframe rendering unchanged while still correcting normal page and media hyperlinks.

For English pages, the index title is read from the rendered HTML rather than copied from Czech MDX frontmatter. If the English postprocess marked a page as incomplete, the cover index and manifest label it as `Incomplete / Czech fallback`. An `/en/` route can therefore exist even when some or all of its article content remains Czech.

The PDF is a paginated visual snapshot, not a lossless replacement for the website or source repository. Wide tables, long source-code lines, and other horizontally overflowing content can be clipped, wrapped differently, or extend beyond the printable area. The generated cover includes this limitation explicitly. The archived HTML, source files, repository, `ALL_POSTS.txt`, and other preservation layers remain the authoritative complete versions.

9.6.4 Ultra-compact PDF export

The project also includes a second PDF exporter designed for high-density archival copies:

```
scripts/export-site-pdf-ultra.py
```

Unlike `scripts/export-site-pdf.py`, this exporter does not reproduce the visual design of each web page. It reads the existing `dist/ALL_POSTS.txt`, reuses the compact serialization implemented by `scripts/filter-all-posts.py`, and lays the selected content out as a dense A4 document. The tool is intended for cases where page count and storage size matter, while images and links should still remain present and usable.

The ultra-compact export:

- uses four text columns and 4 pt body text by default
- starts every article title on a new line
- includes aggressively resized image thumbnails while preserving their natural aspect ratios
- keeps consecutive image groups in regular rows of up to three images
- uses incomplete image rows efficiently by allowing a complete following paragraph to occupy the remaining width, rather than leaving an isolated sentence fragment beside the images
- writes video, PDF, and interactive-media targets as compact clickable text URLs instead of large embed cards
- keeps links clickable without visually underlining them
- omits unrecoverable image placeholders from the PDF and reports their count on the command line

- omits duplicate media by default when the same media occurs in both language versions
- writes an adjacent JSON manifest containing the selection, layout settings, media statistics, output size, page count, link count, and SHA-256 hash

The exporter is manual and is not called by the normal web, USB, Arweave, Gemini, or integrity build workflows. It expects a current standard web build containing:

```
dist/ALL_POSTS.txt
dist/images/
dist/files/
dist/demos/
```

Create or refresh that input before exporting, for example with:

```
npm run build:web:strict
```

The Python packages used by the exporter are Playwright, pypdf, and Pillow. Playwright also requires its Chromium browser:

```
python -m pip install playwright pypdf Pillow
python -m playwright install chromium
```

The recommended high-resolution Czech export is:

```
python scripts/export-site-pdf-ultra.py --lang
cs --image-dpi 400
```

The default output is:

```
exports/vojtamaur-web-export-ultra.pdf
```

The adjacent manifest is written as:

```
exports/vojtamaur-web-export-ultra.manifest.json
```

Language and section selection work in the same style as the normal PDF exporter:

```
python scripts/export-site-pdf-ultra.py --lang
cs
python scripts/export-site-pdf-ultra.py --lang
en
python scripts/export-site-pdf-ultra.py --lang
both
python scripts/export-site-pdf-ultra.py --
section cestovani
python scripts/export-site-pdf-ultra.py --
section volna-tvorba,vystavy
python scripts/export-site-pdf-ultra.py --lang
cs --section cestovani
python scripts/export-site-pdf-ultra.py --
separate
```

`--section` can be repeated or supplied as a comma-separated list. Date selection is available through `--from-date YYYY-MM-DD` and `--to-date YYYY-MM-DD`. `--separate` creates one compact PDF for each selected article and language under `exports/ultra-media-separate/` instead of creating one combined document.

Image quality can be adjusted independently from the physical thumbnail size:

```
```

```
python scripts/export-site-pdf-ultra.py --lang
cs --image-dpi 300 --jpeg-quality 80
```

The default thumbnail raster resolution is 240 DPI and the default JPEG quality is 70. Higher values generally produce sharper images and a larger PDF. `--thumbnail-width-mm` and `--thumbnail-height-mm` control the maximum physical thumbnail box; images are fitted inside that box without changing their original proportions.

The page format, column count, text size, spacing, margins, and page numbers can also be adjusted. All available options and their current defaults can be displayed with:

```
python scripts/export-site-pdf-ultra.py --help
```

The script detects the project root from its own location, so it can be launched from the repository root or directly from the `scripts/` directory. `--project-root` remains available when the script is stored or invoked from another location.

This output is a compact preservation and reading layer, not a lossless replacement for the website, source repository, original media, or `ALL_POSTS.txt`. Text is deliberately very small, images are downsampled, interactive media is represented by links, and missing built assets cannot be embedded. The source files and normal build artifacts remain the authoritative complete versions.

9.6.5 Metaweb archival PDF export

The project includes a dedicated manual exporter for the

metaweb article and the preservation material linked from it:

```
scripts/export-metaweb-pdf.py
```

The exporter reads the existing finished standard web build in `dist/`. It does not run Astro, regenerate integrity metadata, sign the build, or run automatically from any web, USB, Arweave, Gemini, or integrity build command. This preserves the exact relationship between the rendered English page and the identity files already present in the selected build.

Before the first use, install the same Playwright and pypdf dependencies used by the normal PDF exporter:

```
python -m pip install -r requirements-pdf-export.txt
python -m playwright install chromium
```

Run the export manually with:

```
npm run export:pdf:metaweb
```

There is no `generate:metaweb` npm script. The command above is the supported npm entry point for this manual export.

All standard web and USB builds write to the same `dist/` directory, so the most recently run build determines its routing and link format. Do not run the metaweb exporter against `dist/` left by `build:usb`, `build:usb:translate:signed`, or another USB build variant. USB mode uses flat files such as `metawebovy-clanek.html` and rewrites links for `file://`, while the exporter expects the standard directory route `/metawebovy-clanek/`. A typical symptom of using USB output

is `Page.evaluate: Error: Article content container not found.`

Restore a standard translated and signed web build before exporting:

```
npm run build:web:translate:signed
npm run export:pdf:metaweb
```

If the English translation cache is already complete and a new Gemini export is not required, the strict standard build can be used instead:

```
npm run build:web:strict:signed
npm run export:pdf:metaweb
```

The metaweb exporter intentionally does not rebuild or change `dist/` by itself.

Equivalently:

```
python scripts/export-metaweb-pdf.py
```

The default output is one PDF plus an adjacent JSON manifest:

```
exports/vojtamaur-web-export-metaweb.pdf
exports/vojtamaur-web-export-
metaweb.manifest.json
```

The PDF contains:

- a simple white bilingual title page with the article title, author, and public website, followed by a separate bilingual contents page

- the Czech page `/metawebovy-clanek/`
- the postprocessed English page `/en/metawebovy-clanek/`
- a deduplicated appendix of every image linked from the article, with the physical archive ID and item name plus Czech and English descriptions derived from the corresponding article versions, the source filename, and public link
- a bilingual explanatory page followed by `exports/vojtamaur-web-export-ultra.pdf`, the ultra-compact Czech export of every article with its images
- `ARCHIVE.txt`
- the complete rendered technical documentation at `/documentation/`
- every file linked from the article section `INTEGRITA A IDENTITA BUILDU`, including the checksum manifest, detached signature when present, build checksum, JSON metadata, signing status, and public OpenPGP key

The payloads of `ALL_POSTS.txt` and `source/vojtamaur-web-source.zip` are deliberately not appended or embedded. Their descriptions and public links remain visible inside both rendered article versions because they are part of the article itself.

The physical archive registry is wider than an A4 page. During this export only, each table row is converted in the browser DOM into a labeled registry card. The card heading contains the ID and item name; the remaining table headers become field labels. This preserves every original cell and hyperlink while preventing the holder, location, access, and notes fields from being clipped. The

website HTML and source MDX are not modified.

The English postprocessed HTML can split the build-integrity link paragraph at invalid positions and expose stray Markdown backticks. For the PDF only, the exporter normalizes those same six links and their descriptions into a readable list. It does not edit the finished build or change any linked payload.

The first page is a deliberately simple white bilingual title page. The generated timestamp, source build, section counts, notices, and outline are placed on a separate bilingual contents page. The image appendix is discovered from article links rather than a hardcoded filename list. The Czech and English pages point to the same images, so every image target is included only once while its card shows the shared archive item title and separate Czech and English article-derived descriptions. The exporter fails instead of silently creating a monolingual card if an image is missing from either article version. The article thumbnail is not included unless it is also linked from the article body. By default, three linked images are placed on each gallery page.

The combined PDF expects the ultra export at:

```
exports/vojtamaur-web-export-ultra.pdf
```

If that file does not exist, the metaweb exporter creates it automatically before rendering the combined document by running the equivalent of:

```
python scripts/export-site-pdf-ultra.py --lang
cs --image-dpi 400
```

An existing ultra PDF is reused unchanged. Immediately after the bilingual image appendix, the metaweb exporter inserts one generated bilingual introduction page. It identifies the embedded filename and explains that the following pages are an ultra-compact Czech export of every website article with its images. It also states the number of following ultra pages and that their intentionally dense multi-column layout serves as an archival overview. The complete pages of the standalone ultra PDF follow this introduction without being edited or overprinted.

Useful options include:

```
python scripts/export-metaweb-pdf.py --images-per-page 2
python scripts/export-metaweb-pdf.py --images-per-page 4
python scripts/export-metaweb-pdf.py --output exports/metaweb-custom.pdf
python scripts/export-metaweb-pdf.py --site-url https://example.com
python scripts/export-metaweb-pdf.py --no-manifest
```

`ARCHIVE.txt`, checksums, JSON, signatures, and public-key material are rendered completely as wrapping monospace text. Long code blocks and URLs in the technical documentation are also wrapped for A4. The final PDF contains outline bookmarks and validates that no file payload was embedded.

An unsigned build legitimately has no `SHA256SUMS.txt.asc`. If that optional link is present in the article but the file is absent from

the selected build, the PDF includes an explicit absence notice rather than inventing signature content or failing the whole export. Other missing identity files and missing linked images are treated as build errors.

The exporter writes a manifest describing page ranges, including the generated ultra introduction and the unchanged standalone ultra PDF as separate sections, source routes, bilingual linked-image descriptions and hashes, the included ultra PDF and its hash, identity-file hashes, the registry-card validation result, the final PDF hash, and the two deliberately excluded payloads. Use `--no-manifest` only when the adjacent machine-readable record is not wanted; that option also removes a stale adjacent manifest left by an earlier run.

Run all manual exports on Windows

The repository root contains `export-all.bat`. It switches the Windows console and Python standard streams to UTF-8, changes to the repository directory, runs the six manual exports sequentially, and stops immediately if any command fails. The ultra export runs before the metaweb PDF export, so the combined PDF receives the freshly generated ultra PDF rather than a stale copy. The workflow then creates the practical compact Metaweb EPUB and separate compact Czech and English site EPUBs:

```
python scripts/filter-all-posts.py --language en
--section volna-tvorba --format compact
python scripts/export-site-pdf.py --pdf-quality
ebook --image-dpi 150 --jpeg-quality 75 --
```

```
ghostscript "C:\Program Files\gs\gs10.07.1\bin
\gswin64c.exe"
python scripts/export-site-pdf-ultra.py --lang
cs --image-dpi 400
python scripts/export-metaweb-pdf.py
python scripts/export-metaweb-epub.py --image-
quality compact
python scripts/export-site-epub.py --lang both
--image-quality compact
```

Run the complete workflow with:

```
export-all.bat
```

The batch file also reuses the current `dist/` and does not create a web build. If the last build was a USB variant, restore a standard web build before running `export-all.bat`.

9.6.6 Manual EPUB exports

The project includes two manual reflowable EPUB exporters:

```
scripts/export-site-epub.py
scripts/export-metaweb-epub.py
```

Both exporters read the finished HTML and assets from `dist/`. They do not convert the source MDX directly. This preserves the postprocessed English pages and makes the EPUB content reflect the selected finished build. The exporters support both normal directory routes such as `dist/article/index.html` and portable flat routes such as `dist/article.html`.

Install their Python dependencies once. Pillow 11.3 or newer is

required so that any AVIF image discovered in a finished build can be decoded and converted to an EPUB core image format:

```
python -m pip install -r requirements-epub-export.txt
```

The general site exporter also reads article selection metadata from the generated `dist/ALL_POSTS.txt`. Its default command is:

```
npm run export:epub
```

The default `--lang both` selection intentionally creates two independent publications:

```
exports/vojtamaur-web-export-all-cs.epub
exports/vojtamaur-web-export-all-en.epub
exports/vojtamaur-web-export-epub.manifest.json
```

It does not combine the Czech and English website editions into one bilingual book. Language and section selection follow the normal PDF exporter:

```
python scripts/export-site-epub.py --lang cs
python scripts/export-site-epub.py --lang en
python scripts/export-site-epub.py --lang both
python scripts/export-site-epub.py --section cestovani
python scripts/export-site-epub.py --section volna-tvorba,vystavy
python scripts/export-site-epub.py --lang cs --section cestovani
```

```
python scripts/export-site-epub.py --separate
```

Each combined publication begins with a visible generated title/frontmatter and reflowable article index. It contains the same export metadata, limitations, language status, article dates, sections, titles, and built routes as the generated index in the normal site PDF. The routes are internal links to the corresponding EPUB chapters. This is an export index, not a copy of the website homepage. Pass `--no-cover` only when this frontmatter is not wanted.

`--section` can be repeated or comma-separated. `--separate` creates one EPUB per article under `exports/<language>/<section>/`; like the PDF exporter, these single-article files do not receive the combined export index. A custom `--output` can be used only for a combined single-language export, because `--lang both` always has two output files.

As with the PDF exporter, a build command is run only when explicitly requested:

```
python scripts/export-site-epub.py --build-command "npm run build:web:strict"
```

Each book keeps the existing article order and content structure. The technical EPUB transformation:

- adds the generated title/frontmatter and linked article index as the first spine document in combined mode
- places every article in its own XHTML spine document with the correct `lang` and `xml:lang`
- generates EPUB 3 package metadata, manifest, spine,

navigation document, and stable reflowable CSS
- embeds and deduplicates local JPEG, PNG, GIF, SVG, and WebP resources used by article images or direct image links; local AVIF is converted to JPEG or PNG because AVIF is not an EPUB core image format
- rewrites links between included articles to internal EPUB links
- keeps downloads, PDFs, demos, and other non-image payloads as public `https://vojtamaur.cz/` links
- replaces iframes and other interactive embeds with labelled public links because a non-scripted reflowable EPUB cannot preserve their runtime
- removes empty built image placeholders that have no source

The exporter can reduce image size without changing article structure. The default preserves the exact source bytes of EPUB-core image formats; AVIF is the intentional exception and is always converted to JPEG or PNG:

```
--image-quality archive
```

Other presets are:

```
printer   maximum side 2400 px, JPEG quality 90
ebook     maximum side 1600 px, JPEG quality 82
screen    maximum side 1200 px, JPEG quality 72
compact   maximum side 800 px, JPEG quality 60,
static GIF poster frames
```

For example:

```
```

```
python scripts/export-site-epub.py --image-quality ebook
python scripts/export-site-epub.py --image-quality compact
python scripts/export-site-epub.py --lang both --image-quality compact --gif-mode preserve
python scripts/export-site-epub.py --lang cs --image-max-px 1400 --jpeg-quality 78
```

The third command is the recommended practical complete-site export. It creates separate Czech and English EPUB files with compact still images while preserving animated GIFs. Use plain `--image-quality compact` only when the smallest practical files are more important than GIF animation.

`--image-max-px` and `--jpeg-quality` override the selected preset. JPEG files are downscaled and recompressed; PNG files are downscaled losslessly when necessary. The `archive`, `printer`, `ebook`, and `screen` presets preserve animated GIF and SVG resources unchanged. The deliberately lossy `compact` preset converts opaque PNG files to JPEG and, unless overridden, animated GIF files to static first-frame PNG posters. These two decisions can be controlled independently with `--png-mode preserve|jpeg` and `--gif-mode preserve|poster`. Preserved animated GIF files retain their original bytes and therefore remain the main size limit. The JSON manifest records the selected and actually used JPEG quality, original and packaged image byte counts, the number of optimized images, interactive fallbacks, and removed empty placeholders. The Metaweb manifest also records separate source and packaged byte sizes and SHA-256 hashes for every asset, so a converted

or optimized file is never described by the hash of a different representation.

The dedicated Metaweb EPUB remains one bilingual publication:

```
npm run export:epub:metaweb
```

Its default outputs are:

```
exports/vojtamaur-web-export-metaweb.epub
exports/vojtamaur-web-export-
metaweb.manifest.json
```

The Metaweb EPUB follows the semantic section order of `export-metaweb-pdf.py`:

1. bilingual title page
2. bilingual contents and export notes
3. Czech Metaweb article
4. English Metaweb article
5. a visible bilingual image appendix with every locally linked physical-archive image, its Czech and English descriptions, filename, and source URL
6. the complete `ARCHIVE.txt` payload
7. the complete rendered technical documentation from `/documentation/`
8. every file discovered in the article's build identity and integrity section, each as a text appendix with source URL, byte size, SHA-256, and full payload

The publication metadata declares both `cs` and `en`. Both Metaweb article chapters keep their own language and heading

IDs. Their wide physical archive tables are converted to reflowable record cards while preserving every cell and link, all `<details>` blocks are opened, and the malformed English integrity paragraph is normalized to the same six-item list used by the PDF exporter.

The PDF's embedded `vojtamaur-web-export-ultra.pdf` is intentionally not inserted into the EPUB and is not replaced by expanded article chapters. The dense standalone PDF remains a separate publication artifact; the Metaweb EPUB contains no substitute for that section.

As in the PDF exporter, the `ALL_POSTS.txt` and `source/vojtamaur-web-source.zip` payloads are deliberately not appended; their mentions and public links remain in the article. A missing optional `SHA256SUMS.txt.asc` in an unsigned build receives an explicit explanatory appendix instead of invented content.

The Metaweb exporter supports the same image controls. The first command below is the recommended practical Metaweb export:

```
python scripts/export-metaweb-epub.py --image-quality compact --gif-mode preserve
python scripts/export-metaweb-epub.py --image-quality compact
python scripts/export-metaweb-epub.py --image-quality ebook
python scripts/export-metaweb-epub.py --output exports/metaweb-custom.epub
```

```
python scripts/export-metaweb-epub.py --no-manifest
```

The recommended command keeps animated GIFs intact while applying the compact preset to still images. Use plain `--image-quality compact` only when static first-frame posters are acceptable in exchange for a smaller EPUB.

The Metaweb EPUB therefore remains focused on the Metaweb material and its direct archival appendices instead of duplicating the complete website corpus.

Every generated book is validated before it replaces the destination file. When the site exporter creates multiple books, all uniquely named candidates are completed first; a conversion failure changes none of the requested outputs, and a handled failure during installation restores the previous set. JSON manifests are likewise written through unique temporary files and atomically replaced. The built-in validator checks the ZIP/mimetype rules, container and package documents, required metadata, correctly namespaced MathML and inline SVG properties, manifest, spine, navigation item, XML/XHTML well-formedness, duplicate IDs, and all packaged local references. The Metaweb exporter additionally verifies its section counts, visible image count, and deliberate payload exclusions before replacing an existing output. This does not replace a final EPUBCheck run when the external Java validator is available, but malformed or structurally incomplete output is rejected locally.

9.6.7 Gemini capsule and Gopher map generation

The project generates a separate bilingual Gemini capsule and a

Gopher-compatible map layer with:

```
npm run generate:gemini
```

The generator is:

```
scripts/generate-gemini-capsule.mjs
```

The output directory is a sibling of the normal web build:

```
dist/
dist-gemini/
```

`generate:gemini` requires an existing finished standard web build in `dist/`. It does not run Astro or the English translation postprocess by itself. Do not use it against `dist/` left by a USB build. Although the generator can locate both directory-style article files and flat `slug.html` files, USB postprocessing has already changed internal links and asset paths for `file://`. The Gemini command can therefore finish without an error while deriving incorrect web paths from that USB-specific HTML.

For a complete build from source, use:

```
npm run build:gemini
```

This command runs the strict standard web build first and then generates the text edition.

The translating production workflow also generates the text edition automatically. Therefore:

```
npm run build:web:translate:signed
```

builds and translates the normal website, generates `dist-gemini/`, and then signs the checksum manifest belonging to `dist/`.

The Gemini/Gopher text edition is deliberately generated from the finished HTML rather than directly from the MDX body. This preserves the actual postprocessed English output and the rendered behavior of shared Astro components. The generator also reads article frontmatter from `src/content/posts/` for stable slugs, section membership, dates, draft filtering, and ordering.

The default output structure is:

```
dist-gemini/
  index.gmi
  gophermap
  favicon.txt
  keys/
  personal-work/
    index.gmi
    gophermap
    article-slug.gmi
  exhibitions/
    index.gmi
    gophermap
    article-slug.gmi
  travel/
    index.gmi
    gophermap
    article-slug.gmi
```

```
cs/
  index.gmi
  gophermap
  volna-tvorba/
    index.gmi
    gophermap
    article-slug.gmi
  vystavy/
    index.gmi
    gophermap
    article-slug.gmi
  cestovani/
    index.gmi
    gophermap
    article-slug.gmi
```

English is intentionally the default language at the capsule root. Czech pages are stored below `/cs/`. Each article page includes navigation back to the homepage and section, a link to the counterpart language when available, and a link to the full HTTPS web version.

For envs.net, the Gemini capsule is published below the user path rather than directly at the host root. Internal generated Gemini links therefore use the configured prefix `/~vojtamaur` so that links resolve under `gemini://envs.net/~vojtamaur/...` instead of incorrectly resolving under `gemini://envs.net/...`. If the capsule is moved to a host where it is served directly from the Gemini host root, this prefix must be changed or removed in the generator.

The same `dist-gemini/` output can also be uploaded to `public_gopher/`. Gemini clients ignore `gophermap` files as ordinary unrelated files, while the Gopher server uses them as directory menus. The intended envs.net deployment mapping is:

```
dist-gemini/  ->  public_gemini/   ->  gemini://
envs.net/~vojtamaur/
dist-gemini/  ->  public_gopher/   ->  gopher://
envs.net/1/~vojtamaur
```

Gopher item types matter in the generated maps. Directory/menu links use type `1`; plain text or Gemtext files use type `0`; informational separator or label lines use type `i`. Some Gopher clients or web gateways may visibly show the leading `i` on informational lines. For this reason, `gophermap` should remain a thin navigation layer, while the real page content stays in `.gmi` files. Clients such as Lagrange can still display those `.gmi` files as Gemtext after opening them through Gopher.

The Gemini homepage contains:

- the site title and motto
- a language switch
- a short description of the capsule
- a provider-neutral capsule description without host-specific acknowledgements
- the latest nine items for Personal Work, Exhibitions, and Travel
- `SHOW ALL / ZOBRAZIT VŠE` after the previews where the HTML homepage exposes that action
- promotional video links followed by a direct link to the

YouTube playlist
- the full About Me and Contact content directly on the homepage

The generator converts the built HTML into Gemtext using the following rules:

- headings become Gemtext headings, limited to the three heading levels supported by Gemtext
- paragraphs remain paragraphs
- explicit HTML `<br>` elements remain line breaks instead of being collapsed into spaces
- unordered and ordered lists become Gemtext list items
- blockquotes become `>` lines
- `<pre>` and code blocks become Gemtext preformatted blocks
- HTML tables become tab-separated preformatted blocks
- horizontal rules become plain separator lines
- images become active links to the canonical HTTPS asset URL
- image ALT text or captions are retained when useful, and the visible link label also includes the target URL so that the destination remains explicit
- PDF, video, map, Sketchfab, and interactive-demo embeds become external links
- local demo paths such as `/demos/example/example.html` become complete links under `https://vojtamaur.cz/`
- internal article and section links are rewritten to local Gemini routes when a corresponding generated page exists

- unknown internal routes remain HTTPS links to the main website instead of becoming broken Gemini paths
- `mailto:` and `tel:` references remain active Gemtext links without duplicated plain-text copies
- generic embeds without a useful title use their URL as the visible label rather than the meaningless text “Embedded content”

The output is written as UTF-8. One client-specific workaround is applied during final writing: a literal Unicode replacement character `U+FFFD` (`

```
--site-url <url>
```

Because `dist-gemini/` is outside `dist/`, the existing web integrity and signing commands do not cover it. Even when the capsule is produced during `build:web:translate:signed`, the resulting detached signature authenticates only `dist/SHA256SUMS.txt`. A separate checksum or signing workflow for `dist-gemini/` has not been implemented. This applies to both the Gemini files and the generated Gopher map layer.

9.7 Arweave / Permaweb build

The Arweave / Permaweb build is created with:

```
npm run build:arweave
```

This command first runs the strict standard web build, then runs the Arweave postprocess, and finally regenerates integrity files for the finished Arweave output:

```
node scripts/make-arweave-build.mjs
npm run generate:integrity:arweave
```

The script creates a separate output directory:

```
dist-arweave/
```

This directory is intended for upload to ArDrive or another Arweave-compatible upload tool.

The Arweave build exists because a normal web build uses root-relative paths such as:

```
/_astro/...
```

```
/images/...
/files/...
/volna-tvorba/
```

These paths work on a normal domain root such as `https://vojtamaur.cz/`, but they do not work automatically when the site is served below an Arweave manifest transaction URL.

The Arweave postprocess copies the finished `dist/` output into `dist-arweave/` and rewrites root-relative references into relative paths appropriate for the location of each HTML or CSS file.

After this copy-and-rewrite step, the build runs the integrity generator again for `dist-arweave/`. This is necessary because the Arweave postprocess can modify files after the normal web build has already created integrity files for `dist/`.

The integrity files inside `dist-arweave/` belong to the Arweave deployment output itself:

```
dist-arweave/SHA256SUMS.txt
dist-arweave/BUILD_SHA256.txt
dist-arweave/integrity.json
```

The source of truth remains the normal project source. `dist-arweave/` is a generated deployment artifact and should not be edited manually.

---

10. Exact special build logic

The `build:usb` script is defined as a USB-targeted Astro build

followed by postprocessing. In the current translation-aware workflow, the effective order is:

```
set "BUILD_TARGET=usb" && astro build && node scripts/en-postprocess.mjs && node scripts/usb-rewrite.mjs && npm run generate:all-posts && npm run generate:integrity
```

This implies six steps:

1. `BUILD_TARGET=usb` is set
2. the Astro build is run in the mode defined in `astro.config.mjs`
3. `scripts/en-postprocess.mjs` applies the English translation layer using the available cache
4. `scripts/usb-rewrite.mjs` rewrites root-based URLs into relative file paths
5. `scripts/generate-all-posts.mjs` creates `dist/ALL_POSTS.txt` as a plain-text preservation export of the finished build
6. `scripts/generate-integrity.mjs` creates `dist/SHA256SUMS.txt`, `dist/BUILD_SHA256.txt`, and `dist/integrity.json` for the final static output

10.1 What `astro.config.mjs` does in USB mode

When `BUILD_TARGET=usb`, the following are used:

- `trailingSlash: "never"`
- `build.format: "file"`

This means that internal routes are generated as files of the form:

```
slug.html
```

instead of the directory form:

```
slug/index.html
```

10.2 What `scripts/usb-rewrite.mjs` does

The script:

1. goes through all `.html` files in the `dist` directory
2. reads their content
3. rewrites selected root-based paths to relative paths
4. saves the files again

Specific rewrites include:

- generated Astro assets in `/_astro/`
- public assets in `/images/`, `/files/`, `/demos/`, and `/source/`
- homepage links to `/`
- internal links in the form `/slug/`
- nested English paths such as `/en/slug/`

The script calculates the relative path from each HTML file back to the `dist/` root. This matters because a root-level file such as `dist/about.html` needs `./_astro/...`, while a nested file such as `dist/en/about.html` needs `../_astro/...`.

The purpose of this step is to adjust the HTML so that the output works even outside a standard web server with root-relative URLs.

10.3 Exact `build:arweave` logic

The `build:arweave` script is defined as a strict standard web build followed by Arweave-specific postprocessing and a second integrity pass for the final Arweave output. The effective order is:

```
npm run build:web:strict && node scripts/make-arweave-build.mjs && npm run generate:integrity:arweave
```

This implies five main steps:

1. the standard Astro web build is created in `dist/`
2. `scripts/en-postprocess.mjs` verifies or applies the English translation layer according to the strict build workflow
3. `scripts/generate-all-posts.mjs` creates `dist/ALL_POSTS.txt` and `scripts/generate-integrity.mjs` creates integrity files for `dist/`
4. `scripts/make-arweave-build.mjs` copies `dist/` to `dist-arweave/` and rewrites root-relative paths
5. `scripts/generate-integrity.mjs dist-arweave` creates fresh integrity files for the final Arweave output

The second integrity pass matters. The checksum files created during `build:web:strict` describe `dist/`. After `scripts/make-arweave-build.mjs` rewrites files in `dist-arweave/`, those original checksums would no longer be sufficient for the Arweave output. Therefore `dist-arweave/` gets its own `SHA256SUMS.txt`, `BUILD_SHA256.txt`, and `integrity.json`.

The Arweave output keeps the directory-style route model of the normal web build, for example:

```
fotogrammetrie/index.html
en/fotogrammetrie/index.html
```

This is different from the USB build, which uses a file-based output model.

The purpose of `dist-arweave/` is to create a static folder that can be uploaded to ArDrive and then exposed through an Arweave manifest. The manifest should be created at the level where `index.html`, `_astro/`, `images/`, `files/`, `ALL_POSTS.txt`, and `ARCHIVE.txt` are directly present.

10.4 Exact Gemini build logic

The standalone Gemini build is effectively:

```
npm run build:web:strict && npm run
generate:gemini
```

This creates or verifies the strict bilingual HTML build in `dist/` and then replaces `dist-gemini/` with the generated capsule.

For rapid iteration on only the converter, the existing HTML build can be reused:

```
npm run generate:gemini
```

This avoids rebuilding Astro or rerunning translation checks after every parser change.

The translating signed production command reaches the Gemini generator through the underlying translating web build. Its relevant order is:

```
```

```
Astro build
-> English postprocess with missing translations
enabled
-> ALL_POSTS and source-bundle generation
-> integrity generation for dist/
-> Gemini capsule generation in dist-gemini/
-> detached OpenPGP signing of dist/
SHA256SUMS.txt
```

The final signing step remains scoped to the normal web build. `dist-gemini/` is generated in the same workflow but is a separate unsigned artifact.

---

11. English translation workflow

The project has an English version generated at build time. The Czech MDX files remain the source of truth. The English version is a derived static artifact produced from the rendered HTML output.

There are two separate translation layers:

- **Manual UI translation** – stable interface text is kept in `src/lib/i18n.ts`. This covers the header, section names, homepage text, and other short visible strings. The small Czech/English labels inside `OpenPgpContact.astro` are a deliberate local exception because the component shares one cryptographic payload between both homepage variants.
- **Automatic content translation** – article body regions are translated after `astro build` by `scripts/en-`

`postprocess.mjs`. The translated fragments are cached in `translations/en/`.

This separation is intentional. UI text is small and highly visible, so it is translated manually. Article content is larger and less convenient to maintain twice, so it is translated automatically.

11.1 Translation configuration

The translation configuration is stored in:

```
scripts/i18n-config.mjs
```

Important values:

- source language: `CS`
- target language: `EN-US`
- cache directory: `translations/en`
- translated regions: `[data-i18n="translate"]`
- maximum translated fragment size: `80_000` bytes

The translation postprocess protects code, embeds, scripts, styles, SVG, canvas, iframes, and anything marked as `notranslate` or `translate="no"`. Image `alt` text and `thumbnailAlt` metadata are not automatically translated. Captions are translated when they are normal HTML text inside a translated region.

11.1.1 Translation glossary and terminology preservation

Project-specific terminology used by the automatic translation layer is stored in:

```
```

```
translations/glossary-cs-en.tsv
```

The TSV file is the canonical source of the glossary. Each non-empty line contains exactly one Czech source term, one tab character, and one English target term:

```
Volná tvorba	Personal Work
```

The tab must be a real tab character, not a sequence of spaces. Duplicate Czech source terms, empty values, extra columns, and leading or trailing whitespace cause the translation postprocess to fail instead of silently accepting an ambiguous glossary.

The glossary serves two related purposes:

- **translation consistency** – project-specific names and concepts are translated according to the intended terminology rather than according to a generic literal interpretation
- **semantic and archival documentation** – the repository preserves how the author intended a Czech term to be understood in English

For example, `Volná tvorba` is mapped to `Personal Work`, not the superficially literal `Free Creation`. The TSV file therefore documents part of the conceptual structure of the project, not merely a temporary setting for an external translation service. Because it is stored and versioned with the source code, this intended terminology remains available in archived repository copies even if DeepL or the current build environment is no longer available.

The glossary integration is configured in `scripts/i18n-config.mjs`:

```
glossary: {
  enabled: true,
  name: "vojtamaur.cz CS-EN",
  sourceFile: "translations/glossary-cs-en.tsv",
  stateFile: "translations/glossary-cs-
en.state.json"
}
```

During a `build:*:translate` run, `scripts/en-postprocess.mjs`:

1. loads and validates the local TSV file
2. reuses the remote DeepL glossary ID recorded in `translations/glossary-cs-en.state.json` when possible
3. otherwise searches the DeepL account for a glossary with the configured name
4. creates the remote glossary if no matching glossary exists
5. updates the remote glossary when its entries differ from the local TSV source
6. stores the resulting remote ID and local revision in the state file

The remote glossary ID does not need to be set manually as an environment variable. Only `DEEPL_AUTH_KEY` is required. The state JSON file is operational metadata and a reusable pointer to the remote DeepL object; it is not the authoritative glossary content. If the state file is missing, it can be recreated from the

TSV and the DeepL account. If the TSV is missing, the intended terminology is no longer reliably reconstructable from the project source.

Glossary-aware cache invalidation is selective. For each translated fragment, only glossary rows whose Czech source phrase occurs in that fragment contribute to its glossary revision. Changing one glossary entry therefore invalidates translations that use that term without forcing unrelated pages to be translated again.

Translation requests are paced and retried with exponential backoff to reduce DeepL rate-limit failures. If DeepL still returns HTTP `429`, translations completed before the failure remain cached and the same translate command can be run again.

11.2 DeepL API key

The DeepL key is not stored in the repository. It is provided through the `DEEPL_AUTH_KEY` environment variable.

In Windows CMD:

```
cd F:\vojtamaur-web
set "DEEPL_AUTH_KEY=YOUR_DEEPL_KEY"
npm run build:web:translate
```

One-line CMD version:

```
set "DEEPL_AUTH_KEY=YOUR_DEEPL_KEY" && npm run
build:web:translate
```

In PowerShell:

```
```

```
cd F:\vojtamaur-web
$env:DEEPL_AUTH_KEY = "YOUR_DEEPL_KEY"
npm run build:web:translate
```

The key must never be committed to the repository, embedded in client-side JavaScript, or uploaded as a public file.

11.3 Web translation commands

Recommended workflow after changing content:

```
cd F:\vojtamaur-web
set "DEEPL_AUTH_KEY=YOUR_DEEPL_KEY"
npm run build:web:translate
npm run build:web:strict
npm run preview
```

Meaning:

- `npm run build:web:translate` fills missing translation cache entries and writes translated EN HTML into `dist/`.
- `npm run build:web:strict` checks that no translated EN fragment is missing.
- `npm run preview` shows the finished build output.

For normal rebuilds with an already complete cache, `npm run build:web` can be enough. Before publishing, `npm run build:web:strict` is the safer check.

To force a full retranslation, use:

```
npm run build:web:refresh
```

This should be used carefully because it can change existing English output even if the Czech source text did not change. It is not a cache cleanup command.

To inspect unused English translation cache files without deleting them, use:

```
npm run build:web:prune:dry
```

To delete unused, unprotected English translation cache files, use:

```
npm run build:web:prune
```

The prune commands run the strict workflow, so they should only be used when the translation cache is already complete.

11.4 USB translation commands

For the portable build with missing translation generation:

```
cd F:\vojtamaur-web
set "DEEPL_AUTH_KEY=YOUR_DEEPL_KEY"
npm run build:usb:translate
```

For a strict USB check, use:

```
npm run build:usb:strict
```

To inspect unused English translation cache files during the USB workflow, use:

```
npm run build:usb:prune:dry
```

To delete unused, unprotected English translation cache files

during the USB workflow, use:

```
npm run build:usb:prune
```

The USB wrapper scripts run `usb-rewrite.mjs` even if the translation postprocess fails. This prevents `dist/` from being left with broken relative CSS and image paths. A rewritten `dist/` is not proof of a successful translation build; the log must still be checked for `[i18n] Postprocess failed:`.

11.5 Translation cache

Translation cache files are stored in:

```
translations/en/
```

Each cache entry contains the original source fragment, the translated fragment, and metadata about the translation configuration. The cache key is derived from the route, purpose, source fragment, language direction, DeepL options, selector policy revision, and any glossary rows that apply to the fragment.

Practical consequences:

- unchanged content is not sent to DeepL again
- changed Czech content gets a new cache key
- changing a glossary entry invalidates fragments that contain its Czech source term
- changing an unrelated glossary entry does not invalidate every translated page
- changing other translation policy can invalidate old cache entries
- old cache entries can remain in `translations/en/` after

content changes unless the cache is pruned
- deleting `translations/en/` forces translation generation from scratch and should not be used as routine cleanup

The cache is part of the project source, not a public runtime dependency. The published site uses the finished HTML in `dist/`.

11.6 Translation cache pruning

Translation cache pruning is handled by `scripts/en-postprocess.mjs` when the `EN_PRUNE_CACHE` environment variable is enabled. The script records every cache hash that is actually used while processing the current English build output. After that, it can remove cache files that are no longer used by the current site.

Recommended web workflow:

```
npm run build:web:prune:dry
npm run build:web:prune
```

Recommended USB workflow:

```
npm run build:usb:prune:dry
npm run build:usb:prune
```

The dry-run command must be checked first. It prints files that would be deleted and reports a summary such as `cache-kept`, `cache-would-delete`, `cache-locked-kept`, and `cache-invalid-kept`. The non-dry command deletes only unused cache files that are not protected.

A cache file is kept during pruning when at least one of these is true:

- its hash is used by the current build
- the JSON file cannot be read safely
- the cache entry has `manual: true`
- the cache entry has `locked: true`
- the cache entry has `edited: true`

New automatically generated cache entries are marked as not manually edited:

```
"manual": false,
"locked": false,
"edited": false,
"editedAt": null,
"editedBy": null
```

When a translation is manually corrected, the cache entry can be marked like this:

```
"edited": true,
"editedAt": "2026-07-06",
"editedBy": "Vojta"
```

This protects the entry from future pruning even if the current source text changes and the hash is no longer used. `manual: true` and `locked: true` are also respected as stronger preservation markers.

Pruning is meant to keep `translations/en/` searchable and maintainable. It should not change the published HTML except

through the normal strict build process. If the goal is only to remove unused cache files, do not use `build:web:refresh`; refresh can retranslate existing content and change manually checked output.

11.7 Development server versus final build

`npm run dev` is useful for editing layout and content. The final publishing artifact is still the build output in `dist/`.

In some cases, `npm run dev` may correctly display manually translated UI elements and metadata, while article bodies remain untranslated in English routes. This usually means the DeepL postprocess has not been applied to the current output yet.

To verify the real final translated output, use:

npm run build:web:translate npm run preview

11.8 MDX hard line breaks inside translated paragraphs

Avoid using Markdown hard line breaks between a bold pseudo-heading and the text that follows it in translated article content.

Problematic pattern:

```
**2026-03-02: TŘÍDĚNÍ PIXELŮ FOTEK**
Pokusil jsem se pomocí algoritmu roztřídit
pixely fotografií.
```

The two trailing spaces after the bold text are meaningful Markdown. They produce a hard HTML line break:

```
<p><strong>2026-03-02: TŘÍDĚNÍ PIXELŮ FOTEK</
strong><br>
Pokusil jsem se pomocí algoritmu roztřídit
pixely fotografií.</p>
```

This structure is fragile when the fragment is sent through the English translation postprocess. DeepL receives one translated HTML paragraph containing both the bold title and the following sentence. During translation, it may preserve the `<br>` but move part of the translated title across it, producing output such as:

```
<strong>2026-03-02: SORTING PHOTO</
strong><br><strong>PIXELS</strong>
I tried to sort the pixels...
```

The visual result looks like a broken heading even though the browser is only rendering the hard break that already exists in the HTML.

Safer pattern when the bold line is only a compact label:

```
**2026-03-02: TŘÍDĚNÍ PIXELŮ FOTEK**

Pokusil jsem se pomocí algoritmu roztřídit
pixely fotografií.
```

This creates separate paragraphs and does not place a `<br>` between the label and the body text.

Best pattern when the line is structurally a subsection heading:

```
### 2026-03-02: TŘÍDĚNÍ PIXELŮ FOTEK
```

```
Pokusil jsem se pomocí algoritmu roztřídit
pixely fotografií.
```

Use real headings for repeated article sections such as dated concept entries. If the default heading style is too visually large, fix that in CSS instead of simulating headings with bold text and hard breaks.

After changing this kind of structure, verify the generated English output:

```
npm run build:web:translate
npm run build:web:strict
npm run preview
```

If the broken English output persists, check whether an old translation cache entry in `translations/en/` is still being reused. The cache stores translated HTML fragments, so a structural mistake can remain visible until the changed source fragment produces a new cache key or the relevant stale cache entry is removed.

11.9 Marking content as not translatable

Use `NoTranslate.astro` for MDX content that must remain unchanged.

Import it from an MDX file in `src/content/posts/` like this:

```
import NoTranslate from "../../components/
NoTranslate.astro";
```

Inline use:

```
```

```
The term <NoTranslate>anti-language</
NoTranslate> should stay unchanged.
```

Block use:

```
<NoTranslate as="div">
This text should not be sent to DeepL.
It will remain exactly as written.
</NoTranslate>
```

Use `as="div"` for block content. The default element is `span`, which is better suited for inline text.

Typical uses:

- already-English quotations
- code-like output that is not fenced as code
- generated text that should remain in its original form
- names, labels, or conceptual phrases that should not be normalized by DeepL
- very large fragments that would otherwise exceed the translation size limit

11.10 `notranslate` inside `MediaRow`

`MediaRow.astro` is a special case because `type: "text"` items are rendered through `set:html`. That means the `content` value is an HTML string, not an Astro component.

This does not work:

```
<MediaRow
  items={[
```

```
    {
      type: "text",
      content: "<NoTranslate>This will not run
as an Astro component.</NoTranslate>"
    }
  ]}
/>
```

Use a normal HTML marker instead:

```
<MediaRow
  bordered
  items={[
    {
      type: "text",
      content: "28. prosince 2014 jsem v Mombase
vyfotil starou popsanou zeď."
    },
    {
      type: "text",
      content: `
<div class="notranslate" translate="no">
It doesn't matter which religion you claim you
are.
It doesn't matter which country you're coming
from.
It doesn't matter whether you're poor or rich.
It doesn't matter if you're black or white.
We are all the same in the eyes of God.
</div>
      `.trim()
```

```
    },
    {
      type: "text",
      content: "Nezáleží, jakého jsi vyznání.
Nezáleží, z jaké země pocházíš."
    }
  ]}
/>
```

The important part is:

```
<div class="notranslate" translate="no">
  ...
</div>
```

The postprocess recognizes this marker, removes the protected block before sending the fragment to DeepL, and restores it afterward.

11.11 Large fragments

The current maximum translated fragment size is `80_000` bytes. If a translated region is larger, the build fails with an error similar to:

```
EN fragment for /en/example/ is 166405 bytes,
above configured 80000.
```

Preferred solutions:

- mark non-translatable output with `NoTranslate`
- use `<div class="notranslate" translate="no">...</div>` inside `MediaRow` text

items
- split unusually large pages into smaller translated regions if needed

The size guardrail exists to avoid sending oversized and fragile HTML blobs to DeepL.

11.12 Troubleshooting

`DEEPL_AUTH_KEY is not set`

The build tried to create a new translation but no DeepL key was available. Set the key and run the translate command again:

```
set "DEEPL_AUTH_KEY=YOUR_DEEPL_KEY"
npm run build:web:translate
```

`Missing EN translation cache`

Strict mode found an EN page that needs a translation cache entry that does not exist yet. Run:

```
npm run build:web:translate
```

or, for USB:

```
npm run build:usb:translate
```

Then run the strict build again.

`Remote DeepL glossary created from local TSV`

This is an informational message, not an error. The TSV file in the repository is the local source of glossary entries, while DeepL

requires a separate remote glossary object in the account. The message means that no reusable remote object was found through the saved state ID or configured glossary name, so the script created one and stored its ID in:

```
translations/glossary-cs-en.state.json
```

If this message appears on every translate build, check whether the state file is being deleted, whether a different DeepL account or API key is being used, or whether the remote glossary was removed.

`DeepL HTTP 429`

DeepL is rate-limiting translation requests. The script spaces requests apart, retries temporary failures with exponential backoff, and respects the `Retry-After` response header when provided. If all retries still fail, run the same translate command again:

```
npm run build:web:translate
```

Translations completed before the failure are already stored in `translations/en/`. Do not delete the translation cache or glossary state file merely because a `429` occurred; that would discard useful progress and create more requests.

Cache pruning would delete a manually edited translation

First run only the dry-run command:

```
npm run build:web:prune:dry
```

If an unused cache entry still needs to be preserved, open the corresponding JSON file and add `edited: true`, `manual: true`, or `locked: true`. Then run the dry-run command again and check that the file is counted as `cache-locked-kept` instead of `cache-would-delete`.

Header and UI are English, but the article body is Czech

The manual UI dictionary is working, but the automatic content translation did not run or did not have a cache entry. Check the build log and run `build:web:translate`.

Local `dist/` is Czech after `build:web:translate`

Check the end of the build log. If it contains `DEEPL_AUTH_KEY is not set` or another `Postprocess failed` message, the Astro build completed but the translation postprocess failed.

Production is Czech, but local `dist/` is English

The problem is upload or caching, not translation. Upload the entire `dist/` directory again and force overwrite existing files. Avoid “skip if same size” and similar FTP shortcuts. Then test with a cache-busting URL parameter.

Metaweb PDF export reports `Article content container not found`

Check which build command last wrote to `dist/`. A preceding USB build, including `npm run build:usb:translate:signed`, leaves flat-file routes and `file://`-oriented links in that shared directory. The metaweb

PDF exporter expects the standard web layout and cannot find the article at its directory route.

Recreate the standard web build and then rerun the export:

```
npm run build:web:translate:signed
npm run export:pdf:metaweb
```

If the translation cache is complete and strict mode is sufficient, `npm run build:web:strict:signed` can replace the first command. Do not use `npm run generate:metaweb`; that package script does not exist.

Gemini was generated after a USB build

Treat that `dist-gemini/` output as invalid even if `npm run generate:gemini` completed successfully. A USB build rewrites relative links for opening HTML directly from disk, but the Gemini converter resolves them as web links. Rebuild the capsule from a fresh standard web build:

```
npm run build:gemini
```

For a release that may also need to fill missing English translations and sign the standard web build, use `npm run build:web:translate:signed` instead; that workflow already generates `dist-gemini/`. Both commands replace the existing Gemini output, so it does not need to be deleted manually.

11.13 Publishing checklist

Before uploading the web build to FTP:

1. Run `npm run build:web:translate`.
2. Run `npm run build:web:strict`.
3. If translation cache cleanup is needed, run `npm run build:web:prune:dry` and check the summary.
4. If the dry-run looks correct, run `npm run build:web:prune`.
5. Run `npm run preview`.
6. Check that `dist/SHA256SUMS.txt`, `dist/BUILD_SHA256.txt`, and `dist/integrity.json` exist.
7. Open at least one EN article locally.
8. Check that the article body is actually English, not only the header and metadata.
9. Upload the complete `dist/` directory, including the integrity files.
10. Overwrite existing files on the server.

For USB/offline output:

1. Run `npm run build:usb:translate`.
2. Run `npm run build:usb:strict`.
3. If translation cache cleanup is needed, run `npm run build:usb:prune:dry` and check the summary.
4. If the dry-run looks correct, run `npm run build:usb:prune`.
5. Check that `SHA256SUMS.txt`, `BUILD_SHA256.txt`, and `integrity.json` are present in the generated output.
6. Open the generated HTML from disk.
7. Check CSS, images, internal links, and EN article content.

For Arweave / Permaweb output:

1. Run the metadata audit: `python scripts/audit-public-metadata.py --exiftool "D:\Program Files\exiftool\exiftool.exe"`
2. Resolve unintended metadata findings before publishing.
3. Run `npm run build:arweave`.
4. Verify that the log ends with `Arweave build prepared in dist-arweave`.
5. Verify that `dist-arweave/SHA256SUMS.txt`, `dist-arweave/BUILD_SHA256.txt`, and `dist-arweave/integrity.json` exist.
6. Test the build locally under a fake manifest-like subdirectory.
7. Upload only `dist-arweave/` to ArDrive.
8. Create the manifest at the level where `index.html` is directly present.
9. Test the manifest gateway URL.
10. Check several deep routes, English routes, `ALL_POSTS.txt`, `ARCHIVE.txt`, and the integrity files.

---

12. Deploy

12.1 `dist` structure

The `dist/` directory contains the finished build intended for publishing.

Important generated preservation and verification files include:

```
dist/404.html
```

```
dist/ALL_POSTS.txt
dist/SHA256SUMS.txt
dist/BUILD_SHA256.txt
dist/integrity.json
dist/SIGNING_STATUS.txt
dist/SHA256SUMS.txt.asc       # only after an
explicit signed build
dist/keys/vojta-maur-openpgp.asc
dist/keys/vojta-maur-openpgp-fingerprint.txt
dist/source/vojtamaur-web-source.zip
```

The `source/` directory in `dist/` is a generated output directory. It should not be treated as source input or committed as a hand-maintained project directory.

The Gemini capsule is not part of this tree. It is generated separately as the sibling directory `dist-gemini/`, and it is not included in the checksum manifest or detached signature stored in `dist/`.

12.2 Deployment of the standard web build

For the production website, the content corresponding to the standard web build is uploaded to the hosting server.

12.2.1 Neocities mirror limitation

The current Neocities mirror is subject to Neocities file-type restrictions, which reject `.zip` uploads. The following generated file is therefore not present on that mirror:

```
dist/source/vojtamaur-web-source.zip
```

Because the source-package link in the published content is root-relative, the link resolves on the Neocities mirror to `/source/vojtamaur-web-source.zip`. That URL is a known dead link on the Neocities deployment.

The source package remains part of the complete local `dist/` output and other deployments that accept ZIP files. The Neocities deployment must therefore be treated as a partial hosting mirror rather than a byte-for-byte copy of `dist/`. Integrity files generated from the complete build may still list the source ZIP even though Neocities rejected it; this is a known deployment-specific omission, not evidence that the local build is corrupted.

12.2.2 Codeberg Pages deployment

The Codeberg repository is named `pages` and is available at:

```
https://codeberg.org/vojta_maur/pages
```

It contains two different branches with separate purposes:

- `main` – the normal project source, pushed together with the GitHub and GitLab copies
- `pages` – the generated contents of `dist/`, used only by Codeberg Pages

The published website is available at:

```
https://vojta_maur.codeberg.page/
```

The repository name is intentionally `pages`. The normal web build contains root-relative URLs such as `/_astro/...`, `/images/...`, and `/slug/`. If the same build were served from

a repository subpath such as `/vojtamaur-web/`, CSS, images, the web manifest, and internal links would resolve against the domain root and return `404`. Using the special `pages` repository exposes the build at the user-domain root and preserves the same URL model as the production website and the other root-hosted mirrors.

Codeberg Pages is triggered by a repository webhook with the following relevant settings:

```
Target URL: https://vojta_maur.codeberg.page/
Event: push
Branch filter: pages
Content type: application/json
```

The local setup uses two Git worktrees so that the source branch and generated deployment branch can remain checked out at the same time:

```
G:\vojtamaur-web    -> main
G:\vojtamaur-pages  -> pages
```

The deployment helper is:

```
deploy-codeberg-pages.bat
```

It is intended to be stored in the project root. The script:

1. verifies the expected directories, branches, and the `codeberg` remote
2. refuses to deploy while the `main` worktree contains uncommitted changes
3. runs `npm run build` in `G:\vojtamaur-web`

4. resets and cleans only the `pages` worktree
5. copies the finished `dist/` contents into `G:\vojtamaur-pages`
6. creates a deployment commit only when the generated output changed
7. pushes only the `pages` branch to Codeberg

The script does not commit, modify, or push `main`. The normal source publishing workflow therefore remains separate:

```
git status
git add .
git commit -m "Commit message"

git push origin main
git push gitlab main
git push codeberg main

deploy-codeberg-pages.bat
```

An optional deployment commit message can be passed as an argument:

```
deploy-codeberg-pages.bat "Deploy updated website"
```

On a fresh workstation, the `pages` worktree can be recreated after configuring the `codeberg` remote and fetching the remote deployment branch:

```
git remote add codeberg https://codeberg.org/vojta_maur/pages.git
```

```
git fetch codeberg pages
git worktree add -b pages G:\vojtamaur-pages
codeberg/pages
```

If a local `pages` branch already exists, omit `-b pages` and attach the worktree to that existing branch instead. The deployment branch is generated output and should not be merged into `main`.

12.2.3 OpenPGP signing policy

Only build artifacts explicitly produced and signed in the author's controlled local environment are OpenPGP-signed. The private signing key is kept on the author's local storage and is never committed to the repository, copied into the build, or uploaded as a CI secret.

Automated or provider-side deployments that do not run the explicit local signing step are intentionally unsigned. They may still publish the public key and fingerprint because those are public identity material, but their presence does not authenticate that particular build.

A valid signature belongs only to the exact `SHA256SUMS.txt` that was signed. A provider-side rebuild is a different artifact even when it was produced from the same source revision. Generated timestamps and deployment-specific rewriting can also make otherwise equivalent builds byte-wise different.

A mirror that receives an already completed locally signed build without rebuilding or modifying it can preserve the same signature. The absence of `SHA256SUMS.txt.asc` on an

automated deployment therefore does not indicate failed checksum generation; it indicates that the explicit private-key operation was not performed.

12.3 `.htaccess`

For a static Astro website, a minimalist configuration is appropriate. A typical WordPress rewrite rule to `index.php` is not relevant for this type of project.

12.4 Portable build

The portable build can be used as a file-based snapshot or offline copy. However, it is not identical to normal web hosting, and some external services may behave differently.

In the portable build, root-relative paths must be rewritten so that the site works from `file://` URLs. This includes the source package link. A correct portable build must link to the source package relatively, for example:

```
./source/vojtamaur-web-source.zip
```

rather than:

```
/source/vojtamaur-web-source.zip
```

The latter would point to the root of the local drive, such as `C:\source\vojtamaur-web-source.zip` on Windows.

12.5 Arweave / Permaweb deployment

For Arweave deployment, do not upload the normal `dist/` directory directly. Use the generated Arweave-specific output:

```
```

```
dist-arweave/
```

Recommended workflow:

1. run the public asset metadata audit
2. run `npm run build:arweave`
3. verify that `dist-arweave/SHA256SUMS.txt`, `dist-arweave/BUILD_SHA256.txt`, and `dist-arweave/integrity.json` exist
4. optionally test `dist-arweave/` locally under a fake manifest-like subdirectory
5. upload only `dist-arweave/` to a public ArDrive drive
6. create an Arweave manifest at the level where `index.html` is directly present
7. copy the manifest Data TX ID
8. test the site through an Arweave or ArDrive gateway URL

The manifest must be created inside the uploaded build root, not above it. The correct manifest target level contains:

```
index.html
_astro/
images/
files/
ALL_POSTS.txt
ARCHIVE.txt
SHA256SUMS.txt
BUILD_SHA256.txt
integrity.json
```

The uploaded Arweave version is immutable. If a mistake is uploaded, the correction must be published as a new upload and

a new manifest transaction. The old version remains available.

12.6 Gemini capsule deployment

For Gemini deployment, use the generated directory:

```
dist-gemini/
```

The Gemini server document root should correspond to the contents of this directory so that `index.gmi` is the English capsule homepage. The Czech homepage remains available at:

```
/cs/index.gmi
```

A typical update consists of:

1. generating a fresh capsule with `npm run build:gemini`, or generating it through the translating production workflow
2. previewing representative `.gmi` files locally in a Gemini client
3. uploading the contents of `dist-gemini/` through the hosting account's supported transfer method, such as SFTP or FTPS
4. verifying the homepage, language switch, section indexes, several article pages, the YouTube playlist link, direct media links, demo links, and the OpenPGP block

The capsule itself contains text and links. Images, PDFs, videos, maps, 3D models, and interactive HTML demonstrations remain on the normal HTTPS website and are opened through absolute URLs. The Gemini deployment therefore depends on the continued availability of `https://vojtamaur.cz/` for non-text

media, while article text and capsule navigation remain native Gemtext.

The capsule can be updated independently by rerunning `npm run generate:gemini` against an existing current `dist/`. However, publishing from stale HTML would also publish stale translated content, so the complete build command should be preferred for normal releases.

---

13. Known issues and solutions

13.1 YouTube embed in local or file-based mode

A YouTube iframe may fail in local or file-based mode with error 153. In that case, it is recommended to account for a fallback opening of the video via an external link.

13.2 Sketchfab warnings in the console

The Sketchfab iframe may generate console warnings such as:

- permissions policy violation
- deviceorientation blocked
- accelerometer is not allowed

If the viewer works, this is not a project error, but a limitation or behavior of a third party.

13.3 Broken CSS or assets with the wrong base model

If the build uses root-relative paths in an environment where no

standard server root is available, styles, images, and internal links may break.

This affects more than one special output model:

- USB / file-based output
- Arweave / Permaweb output served below a manifest transaction path

For this reason, the portable file-based build is supplemented with `scripts/usb-rewrite.mjs`, and the Arweave build is supplemented with `scripts/make-arweave-build.mjs`.

If CSS, JavaScript, images, source package links, or internal links fail in the Arweave deployment, check whether any root-relative path such as `/_astro/...`, `/images/...`, `/files/...`, `/source/...`, or `/slug/` remained in the generated `dist-arweave/` output.

13.4 Dev server and new articles

If the listing or routes do not match after adding a new `.mdx` file, the recommended first step is to restart the development server.

13.5 Lagrange and the Unicode replacement character

A tested Lagrange client stops rendering the remainder of a normal text line immediately after a literal Unicode replacement character `U+FFFD` (` `). The source `.gmi` remains valid UTF-8, and the same character is allowed by Unicode; this is treated as a client rendering defect rather than malformed Gemtext.

The Gemini generator works around the issue only in the generated capsule by converting each literal `U+FFFD` to the visible ASCII sequence:

```
\uFFFD
```

This preserves the information that the replacement character occurred while preventing the client from truncating the rest of the line. The original MDX, rendered HTML, and other Unicode characters are not modified.

13.6 Lagrange indentation after intentional line breaks

When several normal Gemtext lines originate from intentional `<br>` line breaks inside one HTML paragraph (the equivalent of Shift+Enter), Lagrange may render the later lines with paragraph-like indentation. Kristall renders the same `.gmi` content without this indentation. This is a client-specific rendering difference, not an error in the Gemini generator.

Where the source text genuinely contains separate paragraphs, replacing `<br>` with separate MDX paragraphs improves both HTML and Gemini output. Intentional hard line breaks should remain unchanged if converting them to paragraphs would alter the intended HTML structure.

---

14. Future extensions

Possible future directions for the project:

- translation of image alt texts

- adding alt texts to photographs in the Travel section
- automatic translation of PDF exports, with automatic compression of the translated PDFs to reduce file size
- a wiki with interconnected articles (e.g. `wiki.vojtamaur.cz`)
- evaluation of emerging long-term archival media (e.g. NanoFiche) as costs and availability improve
- evaluation of 5D memory crystal storage, once the technology becomes more affordable and openly accessible
- evaluation of DNA-of-Things storage embedded in physical artworks or materials, once the currently prohibitive cost of custom synthesis and production decreases
- evaluation of future opportunities for inclusion in lunar cultural archives (e.g. the Lunar Codex), if suitable public submission pathways become available
- evaluation of future opportunities for inclusion in space-based cultural archives (e.g. the Arch Mission Foundation), if suitable public submission pathways become available
- creation of a long-form, unedited audiovisual walkthrough of the entire website, with author commentary and additional context for individual works and sections
- self-hosting a Tor Onion Service mirror (e.g. on a Raspberry Pi), exposing the same content from a single .onion address over multiple protocols, including HTTP/HTTPS, Gemini (gemini://…onion), Spartan (spartan://…onion), and Gopher (gopher://…onion)
- automation of Internet Archive Wayback Machine snapshots (Save Page Now), systematically submitting website pages and public mirrors for archival capture

instead of relying on manual submissions
- evaluation of embedding ARCHIVE.txt and/or ALL_POSTS.txt data invisibly within each generated HTML page, allowing individual archived page snapshots to carry a redundant copy of the website's textual archive without affecting the visible page content
- evaluation of embedding ARCHIVE.txt data within robots.txt, taking advantage of the file's frequent retrieval and preservation by web crawlers to provide an additional redundant copy of the website's textual archive
- evaluation of FOREVER as an additional long-term digital preservation service, complementing the existing use of Permanent.org and providing further redundancy through an independent archival provider

---

15. Archival operations

15.1 Preservation priority under constraints

When storage capacity or snapshot quotas make it impossible to preserve the complete site, archive these artifacts in the following order:

1. `ALL_POSTS.txt` – the smallest practical content-preservation layer
2. `ARCHIVE.txt` – the map of repositories, mirrors, snapshots, and archive entry points
3. this technical documentation (`/documentation/` or its source file, `src/pages/documentation.mdx`)

This priority is especially useful for storage-constrained deposits

such as Memory of Mankind and for services such as Perma.cc where the number of available snapshots may be limited.

15.2 Manual mirror updates

Some mirrors do not support automatic deployment from the canonical repository and therefore need to be updated manually. These currently include **ChatGPT Sites, Neocities, ArDrive / Arweave, Pollux.casa, and envs.net**.

The ChatGPT Sites deployment does not update automatically when the canonical repository changes. To refresh it, ask ChatGPT in the Sites chat to load the current state of the canonical repository, save or build a new version, and deploy that version explicitly.

The Vercel mirror requires this root-level `vercel.json`:

```
{
  "buildCommand": "npm run build:web",
  "outputDirectory": "dist",
  "framework": "astro"
}
```

Without this override, Vercel's default Astro build may skip the post-build step that generates `ALL_POSTS.txt`.

Codeberg Pages is also updated separately through `deploy-codeberg-pages.bat`; the complete worktree-based procedure is documented in section 12.2.2.

15.3 External web archives

As an operating assumption, newly published article URLs and mirror URLs should be submitted to the Internet Archive. Seeding the archive with these URLs is expected to improve discovery and may lead to later automatic recrawling, but it is not a guarantee that every URL or later version will be captured.

The Czech Webarchiv likely captured `https://vojtamaur.cz/` after a manual preservation request. Searching for the root URL currently returns the following access notice:

> Tuto stránku Webarchiv nemůže zobrazit. Z důvodu autorského zákona nemůžeme tuto stránku zpřístupnit online. Archivované verze této stránky jsou dostupné pouze z Referenčního centra NK ČR.

This indicates restricted archived holdings rather than public online access; it does not by itself establish the completeness or capture dates of those holdings.

15.4 YouTube video archiving

YouTube videos are downloaded from Windows Command Prompt with `yt-dlp`. Put the video URLs in `urls.txt`, one URL per line, then run:

```
yt-dlp --write-info-json --write-thumbnail --write-description --write-subs --write-auto-subs --sub-langs "cs,en" --embed-metadata --download-archive downloaded.txt -f "bv*+ba/b" -o "%(title).200B [%(id)s]/%(title).200B [%(id)s].%(ext)s" -a urls.txt
```

The `downloaded.txt` archive prevents already recorded videos from being downloaded again.

15.5 Arweave gateway entry points

An Arweave manifest Data TX ID identifies the archived deployment independently of the HTTP gateway used to retrieve it. The current archived deployment uses this manifest Data TX ID:

```
GHwSYFJtzrRqt5AOZuwJfJHoV6Bc5qjwe5FtFP6UjAs
```

`ARCHIVE.txt` and other preservation records should list at least these two entry points to the same manifest:

```
https://
db6beycsnxhli2vxsahgn3ajpsi6qv5alttkr4d3sfwrj7uurqfq.ar
GHwSYFJtzrRqt5AOZuwJfJHoV6Bc5qjwe5FtFP6UjAs/
https://arweave.net/
GHwSYFJtzrRqt5AOZuwJfJHoV6Bc5qjwe5FtFP6UjAs/
```

These URLs are not separate archived copies. They are two HTTP gateway routes to the same manifest and the same underlying Arweave data. If one gateway returns intermittent `404` or `504` responses, or loads HTML while failing to load CSS or other assets, test the identical manifest path through the other gateway before concluding that archived data is missing.

On 2026-08-18, the ArDrive gateway was observed returning alternating `404` and `200` responses for the same immutable CSS path, while the corresponding `arweave.net` path returned `200` consistently. The failing ArDrive responses reported `X-`

`Cache-Status: UPDATING`. This behavior indicates a gateway cache or retrieval failure rather than a change to the permanent stored data.

The manifest Data TX ID is the authoritative archival identifier. Gateway URLs are replaceable access routes and additional gateway entry points may be recorded without uploading the deployment again.

15.6 Arctic World Archive pricing note

For Shared piqlFilm, the observed minimum price is €139. An approximately 0.8 GB package cost €139; 1.19 GB was quoted at €165.48, close to €139/GB; and 9.22 GB was quoted at €1,113.21, which may indicate a different calculation or volume discount at larger sizes. Because the exact public pricing formula is not known, treat these figures as practical observations rather than guaranteed price tiers. To stay at the €139 minimum in practice, keep the package safely below 1 GB.

---

16. Summary

The project is designed as a file-oriented static website. Content is versioned directly in the repository, and the final published form is produced by the build process. This model makes it easier to archive, restore, and migrate the project without relying on a database runtime.

From a maintenance perspective, the following points are especially important:

- content is managed as `.mdx` files
- metadata is validated through content collections
- specialized content is encapsulated in several reusable components
- the project supports a standard web build, a portable file-based build, a derived Arweave / Permaweb deployment build, and a generated bilingual Gemini capsule in `dist-gemini/`
- the Gemini capsule uses English at the root, Czech under `/cs/`, native Gemtext navigation, and HTTPS links for binary media and interactive content
- `build:web:translate:signed` generates the Gemini capsule but signs only the normal `dist/` checksum manifest; `dist-gemini/` is currently a separate unsigned artifact
- Codeberg Pages is deployed separately from the generated `pages` branch through the `deploy-codeberg-pages.bat` worktree workflow
- web and USB builds generate a recursively reconstructable source package at `/source/vojtamaur-web-source.zip`
- when working with new content, it is useful to expect the occasional need to restart the development server
- public assets in `public/images/` and `public/files/` should be checked for unintended embedded metadata before commit
- unused English translation cache entries can be pruned with a dry-run-first workflow, while `manual`, `locked`, and `edited` entries are preserved

This documentation describes the current architecture and operating model of the project in a form suitable for ongoing maintenance, handoff, or future migration.
